connected directly to the power line and is powered by −20 volts. Fig. 9 defines the pin numbers to be brought out and their functions. The method used to modify the BSR X-10 will be described later.

Q3 through Q14 are all 2N2222-type transistors, but they could be any NPN device. Power ratings are minimal because they are on for only about 35 ms. Relays are +12-volt SPST DIP types. RL must be a DPDT type as shown. Any small relay can be used.

Alarms

Not counting lighting control, this system has only two alarms. The burglar alarm is a "warble" type and will drive a 30- or 40-Watt speaker. The speaker is mounted in a weatherproof housing. The fire alarm is a Sonalert which is mounted directly on the hot air ducting of the furnace. The ducting makes a good sound pipe and the alarm is easily heard throughout a medium-sized building. Fig. 8 is the schematic of the warble alarm. It is a modified version of the one found in H.W. Sams' *Solid State Electronic Projects*, 1972, page 52.

Telephone Dialer

An output for a telephone dialer (see Fig. 4) is included for special usage. This line is connected to a small amount of logic which controls an autodialer. The dialer is sold by Radio Shack and is connected so that an audio cassette with prerecorded messages is played over the phone.

Care should be used when operating the dialer. Most states do not allow automatic dialers controlled by computers to dial police and fire services. A friend or relative would be a better choice. No circuit description is included here because of regulations that city, county, and telephone companies have instituted.

BSR X-10 Modifications

The BSR X-10 is modified by first removing a single screw in the bottom of the unit. It will come apart in two sections. The LSI chip and push-buttons are in the top section while the transmitter is in the bottom section. The push-buttons will not fall out since they are mounted on the reverse of the PC board. There is room on the top section to cut a hole large enough to install a 14-pin DIP socket. The pins of the socket are wired to the control pins of the LSI chip using small-gauge stranded wire soldered directly to the pin.

Fig. 9 defines the pins and their functions. It is necessary only to tack-solder this connection. The BSR X-10 will function manually as well as from computer control.

Unused Outputs

Several spare outputs are provided for other devices. A word of caution when using these outputs: All are capable of driving one TTL load and it is advisable to include a 1k series resistor when using any of them for additional functions.

Software Design—Overview

The major function of the software is to generate a clock for reference and to help control all other activities of the alarm system. The clock routine is a modified version of an H8 alarm-clock program written by

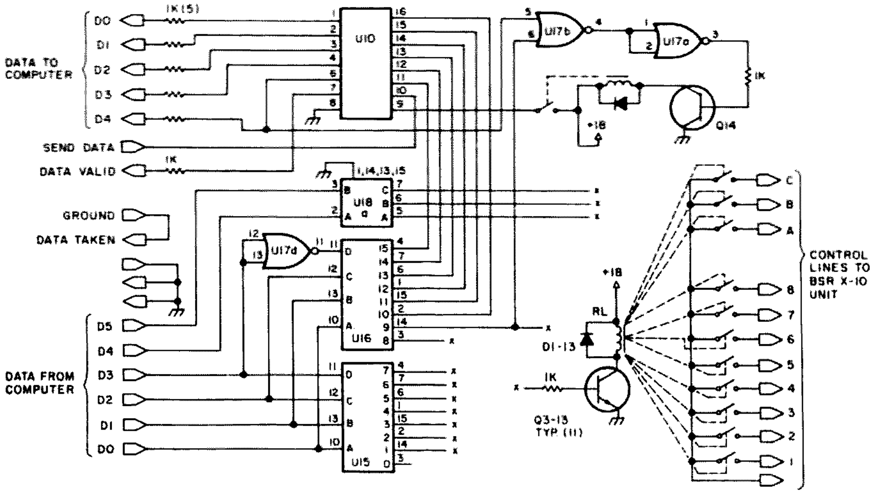

Fig. 7. Part (B), control.

SOFTWARE DESCRIPTION

- Lines 10 through 18 are reminders only. Heath Extended BASIC version 10.05 is used although this software will work on version 10.02 as well as HDOS.
- Lines 20 through 28 allow automatic title centering.
- Lines 30 through 35 are a printed warning for proper port I/O addressing.
- Lines 36 through 46 check to see if the H8-2 will respond. If not, the program stops.
- Line 48 determines the number of days alarm information can be stored. If more time is required, the dimension statement can be changed. The only limit is the amount of memory in the computer.
- Lines 50 through 62 set up and check the time of day that was input from the keyboard.
- Line 64 defines which buttons on the BSR X-10 will be used. The values 33 through 40 equate (see Figs. 9 and 11) to the following buttons: 10, 2, 6, 8, 4, 14, 12, and 16. Any value can be used here.
- Lines 70 through 74 set up the CNTRL-B function and the H8 front-panel readout.
- Lines 80 through 84 check the burglar alarm for operation. If the alarm does not respond, the program stops.
- Line 88 clears the remote-lighting control (BSR X-10) unit.
- Lines 100 through 135 are the alarm check routine.
- Lines 200 through 265 are the clock-counter routine.
- Lines 500 through 595 are the main lighting routine. Note that the lights are not turned on if the time is between the hours of 6 in the morning and 6 in the evening.
- Lines 600 through 695 control when, and the length of time, a randomly-selected light is on.
- Lines 700 through 710 are a subroutine used as a timing routine to allow the relay time to close.
- Lines 800 through 810 are the OFF lighting relay timing routine.
- Lines 1000 through 1060 print the system status when a control-B is used. Any entries are stored in memory and are printed on command.
- Lines 1100 through 1140 are the system error print routines.
- Lines 1200 through 1225 set off the alarm. Before the alarm is actually turned on, the counter (B1) must count eight alarm conditions before the alarm relay is set to ON. This is done to prevent static or power glitches from triggering the alarm. If it is after 6 pm, line 1220 turns all controlled lights on as well as the alarm. Only a control-B or power failure will shut off the alarm. An external switch will silence the speaker but the alarm is still activated.

You will note that the telephone dialer function was not included in the software listing. If it is to be used, it would be added after line 1305 in the case of fire and 1215 in the case of possible burglars. The code would be as follows:

```
1306 OUT 2,x:FOR L = 1 TO 30:NEXT L:OUT 2,0
```

where x will equal the value (decimal) required for the output port selected.

- Lines 1300 through 1310 turn all controlled lights on in case of fire. After the lights are on, the telephone dialer would then be turned on. The program would then return to the timekeeping routine line (200).

\drian Thornton for the December, 1979, issue of *Kilobaud*. The clock time-set outine was modified for 24-hour operation and the alarm routine was modified to control the burglar/fire alarm using the H8 software control-B function. The control-B function also prints out the system status. In my case, the computer is never turned off and the terminal is always on.

Probably the best way to describe the functions of the software program is to go through it line by line

Program listing.

These photos show the IC layout (left) and wire-wrap (right) of board "B". The same techniques are used on this board as were used on the "A" board. The relays are wired using copper strip since they are the PC variety. IC-type relays would use sockets and therefore could be wire-wrapped like the ICs.

(see box). It is written in BASIC, which is an advantage in that there are no speed requirements and modifications are easy to make. The only requirement is that any routine other than the time/tick-counter routine (lines 200 to 260) must be executed in at least 500 ms. If the general format of the program is maintained, the clock accuracy will not be altered.

Several possibilities or methods could be used in the case of fire. It is assumed here that it is night and you are asleep. If a fire starts, the first thing that happens is that the fire alarm goes off. The next is

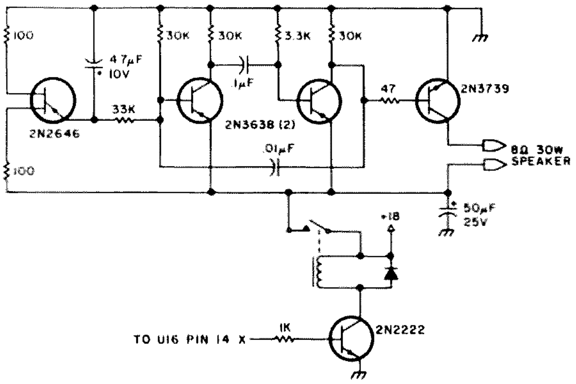

Fig. 8. Warble alarm.

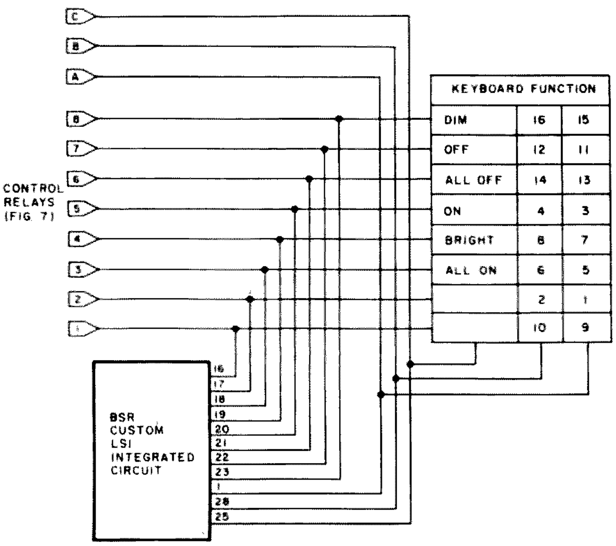

Fig. 9. BSR X-10 control.

SOFTWARE VARIABLES

A	Tick counter
A(1) thru A(8)	Preset light selection
A9	Random number used to determine various selected functions
B	Hi-byte counter
B1	False alarm counter (When count = 8, alarm is set off.)
C	Value read from I/O (alarm system)
C1	Temporary variable used to turn lights off
D	Zone storage element
D1	Hour storage
D2	Minutes storage
D3	Seconds storage
D4	Days storage (24 max.)
L	Relay bounce timing
P	Temporary clock storage
T1	Hours (front panel)
T2	Minutes (front panel)
T3	Seconds (front panel)
T4	Days (internal counter)
X	Temporary clock storage
Y9	Alarm check (1 = on, 0 = off)
Z(1)	Light check (1 = on, 0 = off)
thru	
Z(8)	(All random)
Z(9)	Front porch light status (1 = on, 0 = off)
0$	Set spacing for titles
K$	Same
X$	Same
T$	Variable titles
T1$	Same
T2$	Same
T3$	Same

Decimal Input	C	B	A	8	7	6	5	4	3	2	1	Binary Code	Function
0												000000	Normal state

55	X				X							110111	Off
56	X			X								111000	Dim

Fig. 11. BSR X-10 function chart.

that the lights come on smoke-filled room), then a call (if selected) is made for ou.

In lines 100 through 135, he value of "C" is used to etermine what will happen ext. If the value of "C" quals 8, then the front-orch light is turned on, but nly if it is after six in the evening. If the value of "C" is equal to 16, the fire alarm is set off. If the value is 23, then the self-check message is printed. Any value suitable to your system installation can be used here.

Lines 200 through 265 should not be changed unless you are familar with the operation of the internal tick counter. A complete description of the clock routine can be found in the riginal article referred to earlier.

Random Timing

Line 520 plays an irnportant part in determining hen and if a light will be urned on. The object of his and the following lines to make the house look ived in. A value for A9 of ss than .001 will occur about 6 times in a 24-hour period. If a value less than 01 is generated, line 525 sets A9 to a random integer and then lines 600 rough 616 provide the acal control. These values can be changed to suit individual living patterns.

Line 505 is the line that etermines when the system will self-check. As now et, the system will check tself about 6 to 10 times a ay. Line 585 does the acual checking via OUT 2,15.

Control-B

The function of the control-B is twofold. The first thing that happens is that the alarm is shut off. The next thing is that memory is searched for data. If no data is found, then line 1025 is printed. If some data is found, it is then read out via lines 1030 through 1045. It should be noted that some time will be lost when a control-B is used and there are several different items to list. This is a small problem because the services of the burglar alarm are usually over when this function is required.

Figs. 10 and 11 are the required input codes for the various output functions. Fig. 10 shows the values which control the functions of part (A), and Fig. 11 gives the values required to control the relays attached to the BSR X-10 control system.

Sensor Installation

Sensor installation will depend on several factors, including the types of materials used in the building. Fig. 12 gives examples of the major types of sensors used in this system. Installing the door sensor is about the easiest. Sensor contact is made by attaching small wires to nails or screws which are mounted in the hinge side of the door jamb. A small metal plate attached by nails or two-sided tape is mounted on the door. When the door is closed, the plate shorts across the nail (screw) heads, closing the circuit. Wires from the nails (screws) are run along the floor, rug, or, if necessary, through a small hole drilled in the doorstop. Caulking and paint will easily cover this small wire on the outside of the building.

ecimal Input	U10 Interconnect Pin 16	15	14	13	12	11	Binary Code	Remarks
0							000000	Normal state
9							001001	Sounds alarm
10	HI						001010	
11		HI					001011	Phone dialer
12			HI				001100	
13				HI			001101	
14					HI		001110	
15						HI	001111	System test

Fig. 10. Control functions.

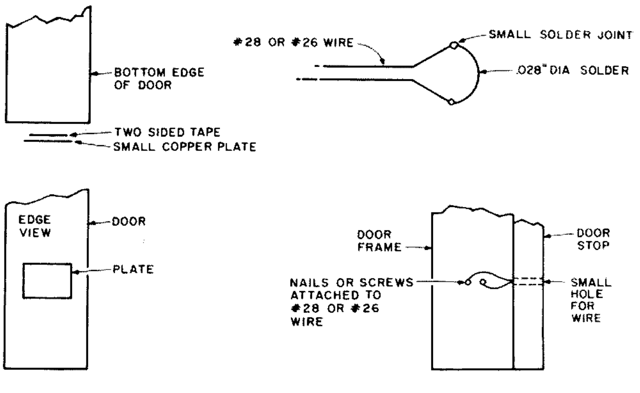

Fig. 12. Fire sensor design (upper right) and sensor-mounting tricks.

Aluminum frame windows and doors are the hardest to wire. If the window or door has an aluminum frame but a wood casing, the same method as used above can be used except that in this case the aluminum frame takes the place of the small plate. If both the frame and casing are aluminum, the best method seems to be mounting the screws on a small insulated block. Careful attention should be given to mounting so that an occasional open or always short circuit will not develop. Conductive tape can be used on windows if necessary. This tape is available from Radio Shack. In any case, use care to conceal the wire. A single wire can be used to loop around one side (zone) of the building with the return being brought directly back to the source (detector enclosure).

The galvanized plates are laid on a plastic mat to prevent current leakage through concrete or wet wood. The entire plate assembly is then covered with indoor/outdoor carpet. The carpet is glued down to prevent slippage.

Summary

This alarm system has been in operation for about one year. Various forms and layouts have been used and as yet only two false alarms were sounded. Both of these were caused by poor solder joints. Power for this alarm is taken directly from the H8 +18- and +8-volt bus. Any source which will provide approximately 500 mA (alarm on) will work. The system is built with CMOS devices and requires less than 1 mA for normal operation.

I hope you enjoy the same peace of mind that I do, should you try this system.■

Parts List

Qty.	Type	Used For	Remarks
ICs			
2	4050B	U1 and U8	
2	4042B	U2 and U3	Pin 6 and 8 to Vss
2	4078B	U4 and U7	
2	4068B	U5 and U6

12	10 V	CR1 through CR12	100-mW zeners
Relays			
10	SPST	+12-volt DIP	
1	DPDT	+12-volt DIP	

Miscellaneous

All resistors are ¼ Watt. Capacitors are in uF and electrolytics are marked with a +. Circuit-Stik products are available in most parts houses or directly from Circuit-Stik, PO Box 3396, Torrance CA 90510. All components can be purchased from Godbout or James or from other advertisers in this magazine.

Diode Doctor

—the P-N diagnoses

Paul M. Danzer N1II
2 Dawn Road
Norwalk CT 06851

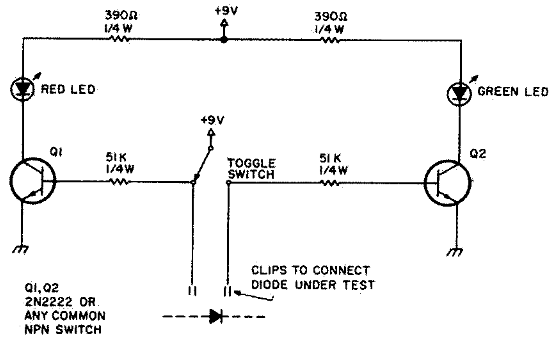

Fig. 1. Diode-tester schematic.

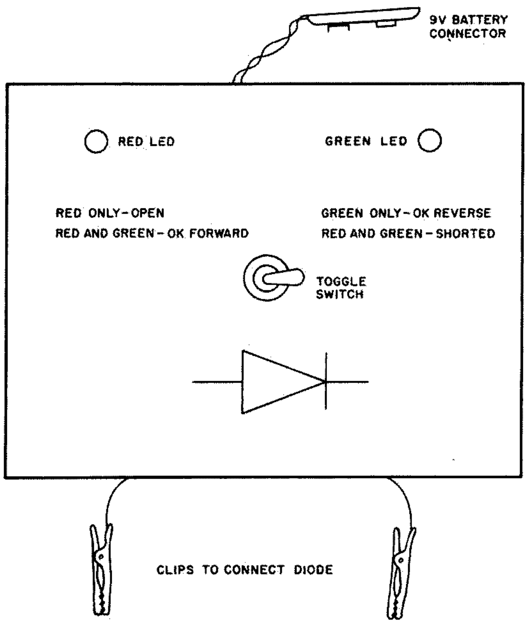

Fig. 2. Front-panel layout.

For many years I have used my ohmmeter to test diodes. The usual technique was to set the meter on R × 10, fumble with the test leads to get a "low" reading (OK in the forward direction), reset the meter to R × 100 or R × 1000, refumble to reverse the diode, and check for a "high" reading (OK in the reverse direction). Usually, around the second fumble I would lose track as to whether I actually reversed the diode and would have to fumble a few more times to recheck.

Recently, I purchased a bag of 100 untested switching diodes, and anticipating a long evening of lead switching, testing, and retesting, I decided to build a simple diode tester. Construction time was about 15 minutes, a good investment if you occasionally or more than occasionally test diodes.

The circuit shown (Fig. 1) was built in a 3" × 4" × 1" plastic box. Three holes are drilled: one for each LED and one for the toggle switch. The "instruction plate" was written on a self-stick label and mounted just above the switch. Two test leads with clips are brought out to connect with the diode as shown by the symbol drawn just below the switch. Fig. 2 shows the physical arrangement of the front panel.

A standard 9-volt battery connector is brought out the back to power the circuit. I recently have standardized all of my small test instruments on 9 volts and bring out the connectors. When I want to use an instrument, I simply connect a 9-volt battery, thus saving on power supplies and multiple batteries for instruments I only occasionally use.

Operation of the tester follows the "instruction plate." Connect the diode, throw the toggle switch to the left, and check that both the red and green LEDs are on. If only the red LED fires, the diode is open. Now throw the toggle to the right; only the green LED should be on. If both the red and green LEDs fire, the diode is shorted. Note: If the diode fails both tests, you probably have connected it backwards. Thus, the tester also can be used to find the polarity of unmarked diodes.

Caution: Many toggle switches connect the center terminal to the end terminal opposite the direction of the toggle handle. When the toggle handle is to the left, the center and right rear contact (as viewed from the front) are connected. Check yours out with an ohmmeter before wiring it in accordance with the schematic.■

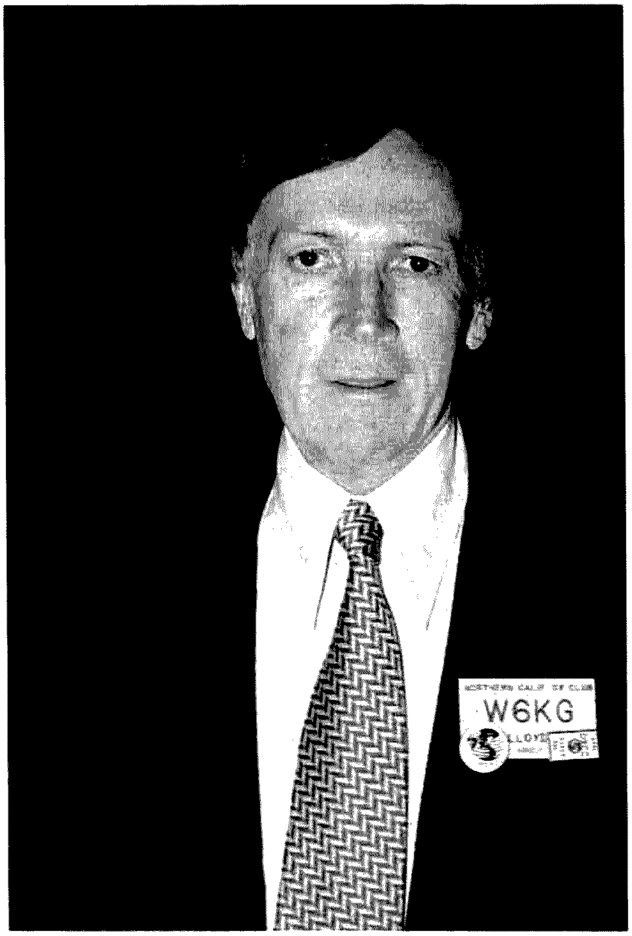
In Profile: Lloyd and Iris Colvin, The DXpeditioners

Lloyd and Iris Colvin are living a dream that all DX-oriented amateurs have envisioned at least once. It's a dream of unlimited travel toward receding horizons, of financial security and international celebrity status. It's a dream of going to the sun, setting up a shack, and, for once, operating as the hunted rather than the hunter. It's a dream of being DX.

For the past 16 years, the Colvins have been on the move. The statistics listed on their Yasme Foundation QSL card tell the story: traveled to 142 countries, worked over half the active amateurs in the world, achieved DXCC 56 times under various callsigns, received over 350,000 QSL cards, worked 354 countries, won 400 awards including the first *CQ Magazine* WPX Certificate.



Lloyd Colvin.

Tanned and healthy, the Colvins approach retirement age with energy and enthusiasm instead of dread. Part of the reason is their lifestyle. Financially secure and unfettered by family or business constraints, they are free to roam the world together in an ongoing DX odyssey.

Under the auspices of a tax-exempt foundation called Yasme, they have made a career of amateur radio DXpeditioning. With an affinity for travel gained during a 23-year military career and a love of radio communications spawned in the early days of amateur radio, the Colvins are uniquely equipped to meet the demands of their gypsy lifestyle. Operating from seldom-heard coral atolls, newly-established African countries, or lavish Caribbean island playgrounds, the Colvins have long fascinated those less-fortunate souls on the opposite end of the circuit.

But what does it take to globe-trot constantly, to be without home and family much of the year? How is it possible to be so dedicated to amateur radio that, no matter how unusual or exotic the locale, rarely a day goes by without time spent at mike or key?

And what of Yasme? Where does the family stop and the Foundation begin? How does this tax-exempt corporation function? Is it a building or a box in the Castro Valley, California, post office? How are the donations used and what degree of financial support does Yasme sponsorship entail?

These questions are just a few of many asked during an afternoon spent with Lloyd and Iris Colvin—the DXpeditioners.

73: Lloyd, what is Yasme all about?

Lloyd: Actually, it all started in 1954. A young fellow named Danny Weil built a 19-foot boat with his own two hands. Danny was an Englishman, and he hoped to sail around the world in the little boat that he had built.

When he got to the US Virgin Islands, he met Dick Spenceley KV4AA. Dick said to Danny, "Why don't you become a radio ham? Then, as you go around the world, people who enjoy speaking with exotic countries would have the chance to do so. They might even help you financially in pursuing your trip around the world."

73: So Danny Weil wasn't licensed when he began the trip?

Lloyd: No. He was not a radio ham and he didn't know the code. But Danny accomplished something about only one man in 100,000 could. He learned the code, got his license, and was on the air working pileups at 20 words per minute within one month after starting from scratch. He then proceeded to go out to many exotic places with a rig and give many people new countries.

Well, Danny never quite made it around the world, but he did sail over 25,000 miles. His boat was called *Yasme*—that's a Japanese word meaning "good luck."

In 1961, the Yasme Foundation was formed. Its main goal was the collection of money to keep Danny going. This worked out well until 1964, when Danny met a young lady on one of his stops and they got married. They went out on a few more voyages together and almost lost their lives in mishaps at sea.

There were five *Yasme* boats from the beginning of Danny's odyssey to the end. All now rest on the ocean floor.

73: Is Danny Weil still alive?

Lloyd: Yes, he's still alive. He is living in Texas now and he's about fifty years of age. He gets on CW frequently, but he does not hold a call of his own in the US.

73: So, in 1964 the Yasme DXpedition torch was passed to you?

Iris: Yes. We had always thought about going out on a DXpedition, and in 1964 I said to Lloyd, "Why don't we go?" We contacted Yasme because we knew it was still active, although no one was out at the time. We asked if they'd sponsor us, and they said yes.

73: What did Yasme sponsorship entail?

Iris: They had no money in the Foundation at that time, but we paid our own way, anyhow, so it didn't matter. They provide a big service for us in the way of QSLs. The donations they receive help with that. They also helped with licensing in countries where we had trouble.

73: So you're operating as independent hams under the umbrella of the Yasme organization?

Iris: Yes, that would describe it well.

73: Are there other people in the same situation in Yasme or are you two the only active DXpeditioners?

Lloyd: There have been others in the past. One of the most noteworthy is George McKercher WØMLY. He is now a director of Yasme. He made a Yasme-sponsored trip to many of the countries of Africa in the 60s. There have been a couple of other people who have gone out under the sponsorship of Yasme, also.

We are finally approaching the activity of Danny Weil. He was out continuously for nine years, you know. We have been out actively from 1965 . . 16 years in all. We frequently take a few months off and go back to California for a rest. We still have a business there that we're connected with.

73: I see. Is Yasme headquartered in California?

Lloyd: It is, but it is incorporated as a nonprofit corporation in Florida.

73: Does Yasme have an office and phone, or is it just a mail drop?

Lloyd: Well, for nearly 16 years now we have had the same PO Box—2025, Castro Valley, California—that's been a help because people always know that they can get a card from us at that address.

73: So, no full-time, paid office staff?

Lloyd: No.

Iris Colvin.

73: You must receive thousands of QSLs each month. How and by whom are they handled?

Lloyd: We have had a number of Yasme people who have helped with the QSLs.

Today, Iris and I have the largest QSL collection in the world. I don't think there is anyone else who has more cards than we do. All of them are arranged in alphabetical order and stored in a huge metal cabinet. Our files number in excess of a third of a million cards at present.

73: That's amazing!

Lloyd: There are some other amazing statistics about our QSL collection. For one, the weight. We're a little worried about the structure of our home which, incidentally, we built. It was designed to carry a good load, but the QSLs we have amassed weigh over a ton!

Also, putting this collection in the state it's in now has taken lots of work. For example, if it takes a minute and a half to answer a card, file it, etc., when we receive one, it would take one person working forty hours a week three years just to file the cards we have received to date.

73: How do you confirm a contact for a new country? Do you check back against the log?

Lloyd: Yes, we do. We use a log system that Yasme has used ever since we've been connected with it. We can thank the infamous Mr. Don Miller W9WNV for designing it. In fact, he gave us the first copy of the log we use. It's a good system and we have used it for as long as we've been operating.

It consists of a small form with attached carbon, about five by seven inches in size. Each sheet holds 100 entries and when a sheet is full, we send the carbon to Yasme for filing and verification.

73: And the folks at Yasme verify the contact and then QSL?

Lloyd: Yes, and Yasme has had over 100 people help with this over the years.

73: Are all these people volunteers, or are they paid?

Lloyd: They are all volunteers. Nobody gets a cent. Nobody has ever received any money in the headquarters of Yasme, either. Right now, we have one lady who is single-handedly answering all of our cards. She is Carolyn Brand WA6AKK.

SOME OF THE COLVIN CALLS

W6KG (Lloyd)—W6QL (Iris)—FA8JD—J2AIH—J2USA—DL4ZC—KG6SV—KC6SZ—VR1Z—GD5ACH—ZB2AX—GC5ACI—CT3AU—CT2YA—6W8CD—5T5KG—ZD3I—9L1KG—5L2KG—9G1KG—TU2CA—5V1KG—TY2KG—VR8B—3D2KG—C21NI—FKØKG—YJ8KG—ZF2CI—W6KG/-AJ3/TI5/6Y5/VP2A

We've just returned from four months of operating during which time we made over 55,000 contacts. This poor lady is receiving over 25,000 QSLs from that trip alone.

Iris: Lloyd, we should also give credit to W6RGC—Bob Vallio. He was our first secretary and he did all of our cards in years gone by.

73: How did you folks acquire the DXpedition lifestyle, the constant going?

Lloyd: We started our world travels while I was in the service. I've had one career in the military and a second afterwards. I was in the Army Signal Corps before World War II. I was a radio ham when I was 12 years old and have been one for 52 years now. Iris became a ham as soon as we got married, so she's been a ham for 37 years.

Actually, I got into the Signal Corps through ham radio. In fact, almost everything we've done in our lives has been directly connected with ham radio. I guess I found my military life interesting because much of it was similar to running ham stations.

73: And I imagine you did a fair amount of traveling during your military years?

Lloyd: That got us started traveling, yes. We've now been to 142 countries, and about half of those were visited while I was in the military service. I spent 23 years in the military and retired in 1961 with the rank of Lieutenant Colonel.

73: How did you get into DXpeditioning?

Iris: When we decided to go on our first DXpedition, in 1965, we sold our house, closed out the five construction contracts we had going, advertised for and found a good home for our dog, and then left. Our intention was to go out indefinitely.

Well, after three an a half years we got tired and went back to California for a rest. Now we have a different house; it's a place we can go back to as a home base and it even has a permanent amateur radio station.

73: You said that you had a business in California. What type of business is it that allows you to be away so much?

Lloyd: Well, when I left the military, we went immediately into the construction business. We started out building homes and then went on to larger projects like apartment houses, hospitals, and office buildings. Today, I'm the president of Drake Builders of California and Iris is the vice president.

> "Almost everything we've done in our lives has been directly connected with ham radio."

73: I see. Since you're away so much, I imagine you must have a reliable manager working for you.

Iris: We're no longer in the construction business. Today we own several apartment buildings which require occasional looking after but not daily attention. My daughter and her husband look after the day-to-day cares of the business. In fact, she's a ham, or was. Her call was W4ZEW, but it has expired. It hasn't been reissued though, so maybe she could get it back.

73: Ham radio seems like the ideal way for her to keep in touch with you when you are in hard-to-reach places, places, say... like China. I assume you folks are interested in China?

Iris: Yes. We've been working on it, but we don't know how to break the permission barrier.

73: Have you personally made any overtures to the Chinese government?

Lloyd: Yes. In fact, we had a rather interesting experience while making an effort to gain permission to go.

Back in the last days of the Nixon administration, I read that Secretary of State Kissinger was going to China. I sat down and wrote a letter, giving him the full story on ham radio. I told him that Iris and I would dearly like to go to China and asked him to please do something to help us get into Red China with an amateur station.

We never knew for sure whether he read our letter, but eventually we got a letter from a fellow in the State Department saying that Secretary Kissinger had directed him to respond to us. He provided us with the names and addresses of the four Chinese that they thought were most likely to be in a position to help us.

We wrote to these four people and after many months received an answer from one of them. It was a very short letter, written in Chinese, about a third of a page long.

Not being able to read Chinese, we assumed that it said no, simply because of its length. We took it to an interpreter and, after it was translated, the third of a page became two full pages. One Chinese character can have the same meaning as a full English sentence.

It was a rather interesting answer, and it went something like this: It said that our letter had been received, and they wished to tell us that when our country saw fit to fulfill all the promises made by President Nixon on his recent trip to China, it was possible that favorable action would be taken on our request to operate.

73: We know what happened to Mr. Nixon after that. How do you assess the political situation there today? Do you sense an easing of tensions?

Lloyd: Right now, the Chinese are operating low-powered transmitters in the 80-meter band, so they know what ham radio is. Though they are not permitted to contact the outside world yet, it is my opinion that the day is coming.

73: Do we need some ping-pong diplomacy in ham radio?

Lloyd: Yes. I think a group of hams going over there the way the ping-pong people did could make great strides in furthering the amateur cause.

Iris: The Chinese don't seem to want their people to contact the outside world. That's the stumbling block. If there were some way we could overcome that... we might get somewhere. Right now, they are just afraid to have their people have any contact with the rest of the world.

73: In all such matters I imagine you've got to be part politician to make any progress. You both must be quite adept at working your way through bureaucracies after all your dealings with foreign governments.

Iris: That's one thing that you've got to do. I remember an instance in Africa back in 1971 when many of the countries were being formed. In one place we visited, we felt that they were willing to let us operate but we sensed that there was another problem.

They simply didn't know how to go about granting an amateur license. They had never had to do it before, having had no amateur service of their own. They didn't even know what a ham license should look like.

We told them that we had licenses from many

other countries that we'd be happy to let them inspect. We did so, and the next day were granted a license that looked much like some of the ones we had left with them.

Lloyd: We sensed that they didn't know how to issue a ham license but we couldn't just say, "Hey, don't you guys even know how to issue an amateur license?" Instead, we said, "Why don't we leave these other licenses with you overnight?" When we finally got our license we saw that they had copied almost word for word from our other licenses. Diplomatically speaking, we came in the back door.

73: It's hard to envision a country without an amateur service, but I suppose they exist, don't they?

Iris: They do, and it's a problem for them to issue licenses to people like us.

73: I'm curious about the scenario of a Colvin DXpedition. What happens when you arrive at a new place? Do you have a tech crew that gets everything up and running for you?

Iris: Sometimes yes, sometimes no. One of the things that we do differently than some smaller operations is that we take a full kilowatt station and a directional antenna along wherever we go. We take a three-element beam, a rotator, a linear, and a transceiver. The whole package weighs about 400 pounds.

It's been a lot of trouble to carry around, and a big expense, too. But, as a result, wherever we have gone we have put out a very good signal and given anybody who wants to work us the opportunity. That's our criterion of operation and that's what we've been doing.

73: Do you ship all this gear ahead or do you travel with it?

Lloyd: We have tried many different ways of doing it. When we can, we ship it ahead, but that isn't always possible. When we put the new country of Tuvalu Island on the air under the call of VR8B, we shipped the gear ahead and, fortunately, it was there when we arrived.

Iris: We prefer to take the gear with us instead of shipping it; that's the ideal way. On the other hand, if you don't have a license when you go in, you may have a problem getting it through customs.

Lloyd: In that connection, we have changed some of our ways of carrying gear. During the first ten years of our operation, we always carried it in the manufacturer's packing material—bulky boxes, Styrofoam® packing, etc.

About two years ago, we found a better way to move the main part of our station. Now, I take the transceiver aboard the plane as carry-on baggage. I don't wrap it up at all, so everyone can see what it is. Iris does the same with the linear.

There are some real advantages to this. First, nobody can ever accuse us of sneaking anything into a country because the gear is right out where everyone can see it. Second, all the large, bulky packing material is eliminated. And most important of all, the gear doesn't get lost. Our personal bags and clothes may, but even if they do, we still have the ham station and, to me, that's most important. You can operate in your underwear, but you can't operate without the rig!

Iris: The hippies have helped us out in this regard.

73: The hippies?

Iris: Yes. It's the "in thing" today to carry one of those great big radios around with music blaring. In the streets of San Francisco these days, there are so many that they interfere with each other. As a result, we have had very little trouble carrying our transceiver around. Everyone assumes it's a radio.

73: Speaking of equipment, what type of gear are you using?

Lloyd: We use an old Heath SB-230 linear that weighs 30 pounds. With all the advanced technology we have today, we still can't find anything that will run a kilowatt and weighs 30 pounds.

When we started, years ago, we were using a Collins. Later we switched to Kenwood, and today we are using a Yaesu. All these rigs worked very well for us, especially when you consider that we have had something in the neighborhood of 400,000 QSOs, all with very little technical trouble. We really take our hats off to the manufacturers.

"We've been forced into being the good guys by Don Miller."

73: Lately, many DXpeditioners seem to be having a large number of power-line-related problems. On your trips, do you take any precautions to limit power-line variations?

Lloyd: No. In fact, we're astounded at how well the equipment we've used has held up under considerable variations of input power.

On our very first trip, we took a Variac with us. Soon thereafter, we eliminated it because we found that the commercial equipment we were using worked well with a variation of input voltages in excess of 15 percent. We don't carry a Variac with us now or take any special measures to protect the rigs.

Everywhere we go we are looking for new, lightweight equipment—anything to improve our ability to carry a station with us. Some of the advances have not been as great as we'd have liked.

For example, we are still using the same antenna that we carried with us 15 years ago because we can't find one that is smaller or better. When an antenna comes along that is lighter and better than the Hy-Gain TH-3, we'll buy it immediately!

73: I've always been mystified by the DXpedition that goes to an exotic place, whose members then lock themselves in a room with a rig for a week. They see very little, if anything, of the country. When you are on a DXpedition, do you get around the country and meet the people?

Iris: We sure do. That's the reason that we usually try to stay at least a month in a place. It gives us an opportunity to rent a house or apartment and get out and around. We more or less live with the people wherever we go.

We do like to contact as many people as possible and, in a month's time, most of those who wish to, contact us. We still have time for sightseeing, though, even when we operate 12 hours a day.

Lloyd: And, when we've left a country, our memories are of the people we've met there, not of the actual on-the-air operation. When we look back on it afterwards, it's the people we've met that seem to be the outstanding thing about the visit.

73: You two have been referred to as the premier ambassadors of amateur radio. How do you feel about that?

Lloyd: Well, we have been forced into being the good guys by Don Miller. When he was out he frequently ran into trouble with both the local authorities and his fellow hams. He was occasionally not licensed for, or even located in, some of

the places he claimed to operate from.

We once spent two and a half months in a rare country, with our gear, and couldn't get a license. In spite of that, we never fell for the temptation of getting on the air illegally. We've always had legitimate licenses on all our trips. We also have made it a special point not to commit any type of minor crime in any country we visit, such as operating without proper permission or not paying all our bills.

73: I imagine it's hard to keep up with all the different rules of these countries with regard to frequencies available.

Lloyd: It's not so much keeping up but rather dealing with the annoyance of being in a country where you can't operate on a frequency that you did the previous month in another country. For instance, there are some countries now that allow their amateurs only a 100-kHz segment of 80 meters. During our operations, it is a great temptation to try to go where the Americans are operating on 80 meters, but often we are unable to do this—and we don't.

73: Strictly by the rules then?

Lloyd: Only where the local government says you're supposed to operate, yes.

73: I'd like to hear your views on the bogus DX QSL card incident. Dave Gardner's claim that the scam was merely an effort to demonstrate to the ARRL the shortcomings of its own DXCC program met with little sympathy in most circles.

Lloyd: I have no sympathy for him, I'll tell you that.

73: Were you at the 1980 Fresno DX Convention where the plot was supposedly hatched in a secret meeting?

Lloyd: I was at the Fresno convention, but I heard nothing about a secret meeting, much less bogus QSL operation. If I had, I'd have probably gone to the League myself. What Dr. Dave Gardner did was just plain cheating, and you can quote me on that.

73: In a statement to HR Report, *Gardner implied that a large number of DXers and DXpeditioners were involved. Do you think this is the case?*

Lloyd: I doubt it. I think this was his idea and his operation. The sad thing is that as a result of all of this, people are going to lose faith in DXing and also in amateur radio. The impact of this will be terrible for amateur radio.

73: How do you feel about the no-code license?

Lloyd: We are not in favor of it. It seems to me that we must not lower the standards of amateur radio to those of CB. We have a little something special with the code requirement. Though many say CW is a thing of the past and we don't need it, it never seems to disappear completely.

73: Do you feel that in this era of liberalization it is difficult to maintain standards in amateur radio?

Lloyd: To a degree. However, I don't go along with those who say that the conditions on the bands today are worse than in years gone by. As I look back at my early days in the hobby, and I started in 1929, I'd have to say that it was just as bad or worse back then. People have just forgotten.

In 1929, when two people in the same city got on the air they QRMed each other so badly that neither could hear anything, even if they were on opposite ends of the band. It's simply not true to say that things are worse today than in the old days.

As far as politeness goes, we are in no worse shape today than we were in 1929. When I first became a radio amateur, we had 35,000 hams in this country—that's all. We have ten times that number today, and while there are more troublemakers around, the ratio is just about the same as it was in 1929. I don't really think that conditions today are any worse than when I started.

73: Iris, I read an interesting statistic recently in QST. *They conducted a survey of amateurs and found that the number of women becoming involved in ham radio is on the increase. Any comment on that?*

Iris: Oh, I think that is definitely true. I also think that women are becoming better operators, too. I usually try to contact the YLs, and I've noticed recently that the YLs are much more self-confident in pileups. They talk slowly, seem more poised, and in general are capable of making contacts in good style.

73: How about plans for the future? Other than China, are the Colvins planning anything exciting?

Lloyd: We laughingly tell everyone we meet that we hope to operate from every country in the world. We know this is an impossibility, but it is a goal that we can keep in front of us—something to make life and ham radio more exciting.

"We must not lower the standards of amateur radio."

73: So, as you look down the road, you see more of the same: the travel, the DX operations, the going?

Lloyd: That's right, yes. ■

Ringo Ranger Redux

—add those radials for better performance

After reading the very excellent article by Robert Glorioso W1IS in the May issue of *73*, and having a Ringo Ranger, my interest was stimulated to experiment with adding ground-plane radials.

I cut six pieces of aluminum wire to lengths of 20 inches (50.8 cm). As an aid to spacing them around the base mounting of the antenna equally, I placed a strip of 1" masking tape around the base, brought the ends together, and marked them as shown in Fig. 1(a).

Using a marking pencil, I made a line to indicate where one radial was to be placed. Removing the tape, I then made lines equally subdividing the distance between the two original marks—see Fig. 1(b). The marked tape was then placed on the base mount of the antenna as shown in Photo A.

Next, I placed a 2" hose clamp above the marked tape, but did not tighten it. I slid the aluminum rods under it one by one at the marks, holding each in place with a piece of masking tape. When all six rods were in place and aligned, I secured them by tightening the hose clamp, as shown in Photo B.

Using the handle of an adjustable square which had a designed angle of 45°, I bent each rod to a 45° angle as shown in Photo C.

My findings on adding radials to the Ringo Ranger were the same as those of W1IS. There is an improvement in received signals from repeaters and considerable improvement when working simplex.■

CONTESTING

Ahhh, the weekend. Two solid days to ignore work and tune the airwaves. What? The XYL has chores? Too bad. Today's the day to have some long anticipated rag-chews. Anyway, it looks like rain.

But one flick of the power switch finishes all those pleasant thoughts. No rag-chews today—*it's another contest weekend!* A spectrum full of anxious amateurs, eager to give anything that talks a 59 signal report.

Not since the incentive licensing debacle have feelings run so high. Contesting is one of those searing issues that immediately crystalizes amateur radio into two opposing camps. The only middle ground is here, in FUN!, where both lovers and haters can prove their contesting knowledge.

ELEMENT 1—CROSSWORD PUZZLE (Illustration 1)

Across

1) Contest bonuses
7) Unhardy contester
10) 1970s U.S. prefix
11) Popular contest starting day
12) Pacific prefix
14) Popular antenna
17) Night (abbr.)
18) Civil defense (abbr.)
20) Call-oriented test (2 words)
21) Preliminary result: ____ score
23) Guatemala prefix
24) Twice-worked stations

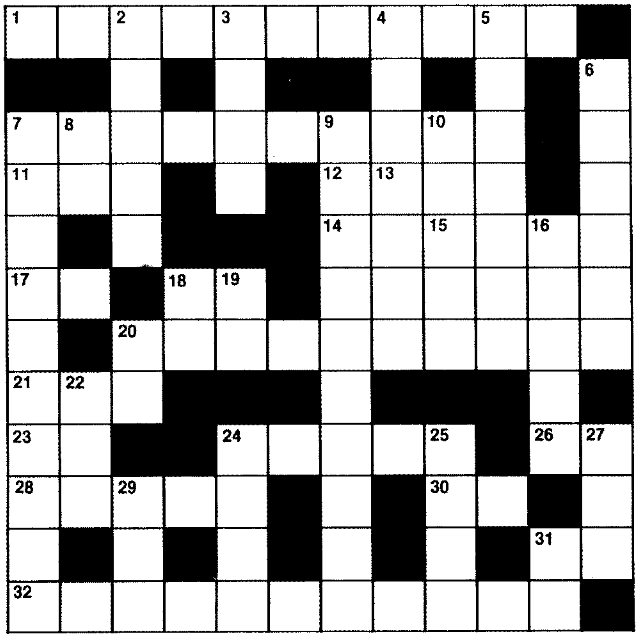

Illustration 1.

ELEMENT 2—TRUE-FALSE

True False

1) It's quite legal for contest organizers to offer prizes. ______ ______
2) A Novice won the 1954 ARRL CW Sweepstakes. ______ ______
3) Most contest organizations disqualify entrants submitting logs with errors totaling more than 2%. ______ ______
4) The North American Sprint is sponsored by the *National Contest Journal.* ______ ______
5) It's possible to enter many contests without even transmitting. ______ ______
6) The March, 1921, *QST* suggested a CQ party. On April 1, according to a specific schedule, all amateurs in a given call district would send CQ. ______ ______
7) The first ARRL Sweepstakes was held in January, 1930. ______ ______
8) The winning operator in the first Sweepstakes worked 153 stations in 43 sections. ______ ______
9) The first Field Day took place in January, 1933. ______ ______
10) The first winning Field Day station had six operators and accumulated a grand total of 60 contacts. ______ ______
11) The Radio Society of Great Britain and the ARRL once cosponsored a contest. ______ ______
12) The 1952 Novice Roundup had 100% greater participation than the previous year. ______ ______
13) In November, 1931, the ARRL sponsored a "Crossband Get-Acquainted Party" to "promote fraternalism and versatility" between 40- and 80-meter operators. ______ ______
14) From 1942 through 1945, U.S. hams were forbidden to have contest QSOs with German and Japanese stations. ______ ______
15) The 1977 Novice Roundup was the first to include Technicians. ______ ______
16) The ARRL, *CQ Magazine*, and *73 Magazine* have all sponsored 160-meter contests. ______ ______
17) The ARRL "Copying Bee" was a receiving contest that specialized in tricky text and code combinations. ______ ______
18) The VHF Marathon was a 1946 contest that lasted eight months. ______ ______
19) The Southpaw Fist Contest is devoted entirely to left-handed brasspounders. ______ ______
20) The NBVM Sweepstakes is a contest for narrow-band voice modulation devotees. ______ ______

ELEMENT 3—SCRAMBLED WORDS

Unscramble these words associated with contest operating.

foceef	olg	mutrecop
coclk	phrocmenoi	eyerk
linpce	peadenohsh	tations
	neatnan	

ELEMENT 4—MATCHING

Match the contests listed below with the month in which they take place.

Column A	Column B
1) Field Day	A) January
2) IARU Radiosport	B) February
3) *CQ* WPX (Phone)	C) March
4) ARRL Novice Roundup	D) April
5) *CQ* Worldwide (CW)	E) May
6) CAN-AM Contest (CW)	F) June

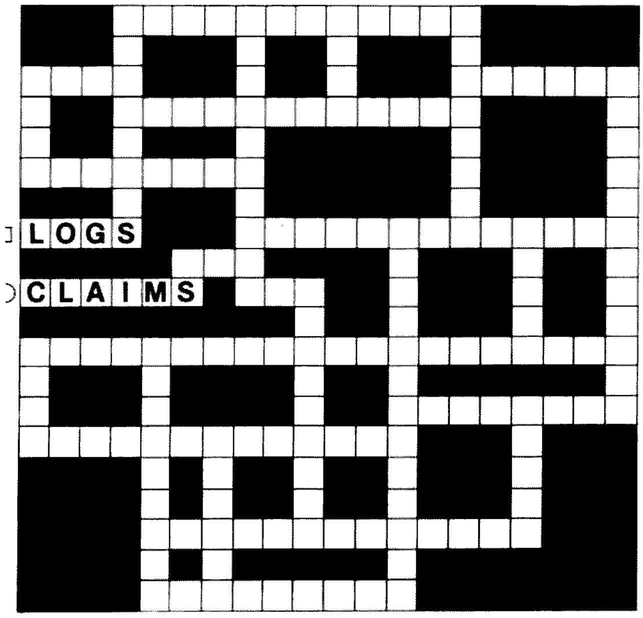
ELEMENT 5—HAMAZE

Here's a new type of maze geared specifically to hams. The object is to start at the circle and trace your way to the square by filling in the answers to the clues given below. To help you on the way, we've already given you the first and last clue answers. All words read either vertically downward or from left to right. Each new word is on a *perpendicular* angle to the previous word. Words join on a common letter. Good luck.

1) Contest records (given)
2) Sometime domestic multipliers
3) Specialized mode
4) West coast contesters (abbr.)
5) Station timepiece
6) Automatic key
7) Station's heart
8) To make advances
9) Novice contester's speed
10) European award (abbr.)
11) Contest QSO
12) Top ticket
13) Topside metal
14) Beam reckoning
15) Total
16) Ham letter words
17) DX encounter
18) Contest sleep
19) What you're reading
20) Output (abbr.)
21) QSOs ____ minute
22) Postscript (abbr.)
23) Sources of assertion (abbr.) (given)



SCORING

Element 1:
Twenty points for the completed puzzle, or 1/2 point for each question correctly answered.

Element 2:
One point for each correct answer.

Element 3:
Two points for each word unscrambled.

Element 4:
Two points for each contest matched to its correct month.

Element 5:
Twenty points for the completed puzzle, or one point for each word.

How did you do in this contest?

1-20	points—"Why is the League wasting my dues on these contests?"
21-40	points—"Contests? I can take 'em or leave 'em."
41-60	points—Third place—Manitoba QSO Party.
61-80	points—"Mr. Clean Sweep."
81-100+	points—They won't let you enter any more contests—you're too good.

FUN! MAILBOX

I think Dave Mann's shot at you in the July "Leaky Lines" was uncalled for. To me, your column will always have taste.

Jonathan Bird KA0BYW
Hopkins MN

As my nephew, Paul David Mann (no kidding) always says: "With a little MSG, it'll even taste better."—J.E.

THE ANSWERS

Element 1:
See illustration 1A.

Element 2:
1—False Not in the United States. Actually, small prizes such as plaques and cups are okay, but the FCC tends to frown on anything more substantial.

M	U	L	T	I	P	L	I	E	R	S	■
■	■	A	■	O	■	■	D	■	A	■	C

Illustration 1A.

2—False But it would have been something.
3—True Be careful.
4—True Great contest and a great group.
5—True Sure. Haven't you ever heard of SWLs?
6—True We think it was meant as a joke.
7—True It was designed as an exercise in traffic handling.
8—True Today, even I do better than that.
9—False No, June, 1933. January's too nippy.
10—True Portable work was tough in those days.
11—True In 1934, a 10-meter contest.
12—True Since 1952 was the Roundup's first year...
13—True Could we make that up?
14—True And because of World War II, anyone else, too.
15—True Techs got their low-band privileges the summer before.
16—True And W1BB has worked them all.
17—True Fifty years ago—sounds like fun.
18—True I wonder when they slept?
19—False Gee, I could enter that one.
20—False It would have to be an ARRL contest.

Element 3:
(Reading from left to right) coffee, log, computer; clock, microphone, keyer; pencil, headphones, station; antenna.

Element 4:
1—F, 2—G, 3—C, 4—B, 5—J, 6—H, 7—A, 8—K, 9—I, 10—E.

Element 5:
See Illustration 2A.

WORLDWIDE AWARDS DIRECTORY

Award hunting may have become the most favorite pastime of radio amateurs, and the need for a consolidated source of information is apparent. To date, I know of three major sources In which such information is available.

The Worldwide Awards Directory, Volume 1, is now available. It lists over 100 awards, and more will be featured in consecutive volumes to be published at later dates. Its cost, $9.95, should be sent to its publisher, KB0ZP, at 736—39th Street, West Des Moines IA 50265.

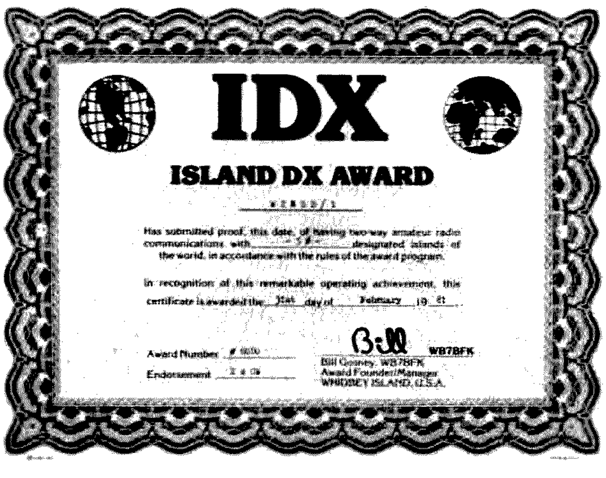
INTERNATIONAL DIRECTORY OF AWARDS

This manual features various award programs throughout the world, and segments its contents by continents of the world. Updates to the manual will be issued in the form of a newsletter and may be inserted within the manual. The basic directory is $8.00 or 32 IRCs while the newsletters (published twice annually) will be $4.00 per year. For additional information, contact the directory's publisher, Vance LePierre W5IJU, 2618 McGregor Blvd., Fernandina Beach FL 32034.

THE DX AWARDS GUIDE

The third and probably the most complete source of information is a series of volumes made available by Chuck Ellis of Ames, Iowa. This directory not only details each award program in detail but also provides a very fine facsimile of the award applications. I've utilized its contents numerous times while filing for various parchments and believe me, the work that Chuck put in his publication has cut processing time dramatically. I am positive that the various award sponsors, as well, are appreciative of the effort of providing a uniform application. There is nothing more cumbersome than trying to sort through various application formats all submitted for the same award.

The DX Awards Guide is featured in great detail on page 128 of the July, 1981, edition of this



magazine.

ISLAND DX AWARD

Of all the DX awards being offered these days, one of the newest and fastest-growing awards programs is that of the Island DX Award: Sponsored by the Whidbey Island DX Club, available to licensed amateurs and shortwave listening stations worldwide, awards are issued for 2 × SSB, 2 × CW, 2 × RTTY, and 2 × SSTV, as well as mixed and single-band accomplishments.

Fifty (50) IDX islands as they appear in the IDX Island listing are required for the basic award. Recognition is given for contacts made in increments of 50 Islands, up to and including the maximum number of islands possible. All DXCC countries which are bona-fide "islands" are the only qualifying contacts. See the IDX listing in this column.

To apply for the IDX Award, prepare a list of contacts in *prefix order*. Include the call of the station worked, IDX island name, band, mode, date, and GMT. Please *number your contacts* 1 through 50, etc. *Do not send QSL cards!* Have your list of islands verified by at least two amateurs or a local radio club official. Confirmation of each contact must be in the applicant's possession and confirmed by verifying signatures.

Send your verified list of contacts with $4.00 (US funds only) and a large self-addressed, stamped envelope (3½" × 9") to the following address. (Foreign stations may substitute the fee by enclosing twelve IRCs.) Whidbey Island DX Club, 2665 North Busby Road, Oak Harbor WA 98277. Rules governing this awards program are reviewed annually in September. Please enclose an SASE with any inquiries regarding the IDX Awards program.

Island DX Listing. The IDX Award program depicts DXCC countries which are bona-fide "islands" as recognized by the National Geographic Society. First criterion, however: They must be a DXCC country as stated on the ARRL DX Countries List. Any qualifying DXCC countries either omitted from this list by error or those which have been recognized for DXCC after the release of this listing will be added to the IDX List when it is printed next.

THE CERTIFICATE HUNTERS CLUB

Thanks to Scott Douglas KB7SB, who is the Western States County Award Manager for CHC, we are able to bring to you an extravagant series of operating awards which will obviously win the approval of every county hunter in the world!

Washington State Award

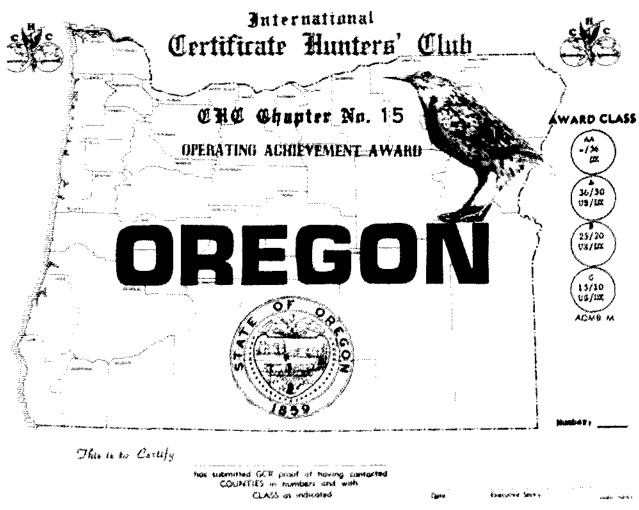
Class D requires 10 to 15 counties; Class C requires 15 to 20 counties; Class B requires 20 to 30 counties; Class A requires 30 to 43 counties; Class AA requires all 44 counties to be worked.

Oregon State Award

Class C requires 10 to 15 counties; Class **B** requires 20 to 25 counties; Class A requires 30 to 35 counties; Class AA requires all 36 counties to be worked.

California State Award

Class D requires 20 to 28 counties; Class C requires 30 to 38 counties; Class B requires 40



IDX AWARD RECIPIENTS

Over the months, many letters have been received requesting a published list of those stations that have qualified for the IDX Award. In callsign order, here are the IDX recipients. Is your call on this honor roll?

to 48 counties; Class A requires 48 to 57 counties; Class AA requires all 58 counties to be worked.

Arizona State Award

Class C requires 5 counties; Class B requires 8 counties; Class A requires 10 counties; Class AA requires 13 counties to be worked.

Nevada State Award

Class C requires 8 to 10 counties; Class B requires 10 to 15 counties; Class A requires 15 to 17 counties to be worked.

Utah State

Class C requires 7 to 10 counties; Class B requires 18 to 24 counties; Class A requires 22 to 29 counties to be worked.

Wyoming State

Class C requires 7 to 10 counties; Class B requires 15 to 20 counties; Class A requires 20 to 23 counties to be worked.

Idaho State

Class C requires 15 to 20 counties; Class B requires 20 to 30 counties; Class A requires 30 to 43 counties; Class AA requires 44 counties to be worked.

Montana State

Class D requires 15 to 20 counties; Class C requires 20 to 30 counties; Class B requires 30 to 40 counties; Class A requires 40 to 55 counties; Class AA requires 56 counties to be worked.

Alaska State

Issued by actual counties contacted, this award may be obtained for two or more counties confirmed.

Hawaii State

Issued by actual counties contacted, this award may be obtained for two or more counties confirmed.

Rules:

1) Awards are available to licensed amateurs and SWLs (on a heard basis).
2) Do not send QSL cards. A list showing full details of the contacts, signed by your local club official or two licensed amateurs, should be submitted.
3) Certificates will be endorsed for various bands and modes as requested, providing such request accompanies application and necessary listings are made.
4) Award Fee is $3.00 worldwide.
5) Endorsements after original application are $1.00.
6) Send application to Awards Manager, Scott R. Douglas, Jr. KB7SB, PO Box 46032, Los Angeles CA 90046, USA.

CHC AWARD SERIES

Worked USA Award

Districts: Issued for contact with all US call districts 1 through Ø.

States: Issued for the total states worked.

Capitals: Issued for the total of capitals of states worked.

Prefixes: Issued for the total number of US prefixes worked.

There is no fee for these awards and they are available to licensed amateurs and SWLs worldwide. A USA SASE is required; worldwide, 3 IRCs are required along with an SAE.

Presidents Award

Issued for the total number of cities worked bearing the last names of past presidents. There is no fee. Same rules as Worked USA Award.

State Cities

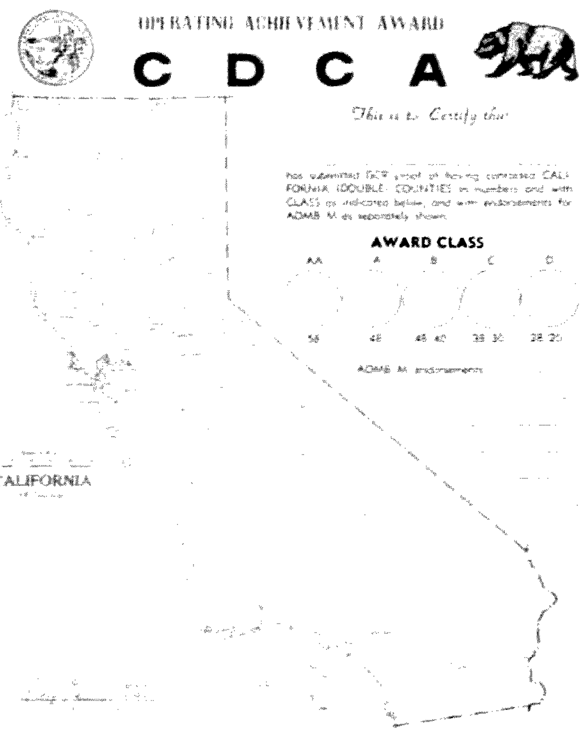
Issued for the total number of cities worked. Awards are issued by state (all 6th & 7th district callsigns). There is no fee for this award but same rules as USA Award.

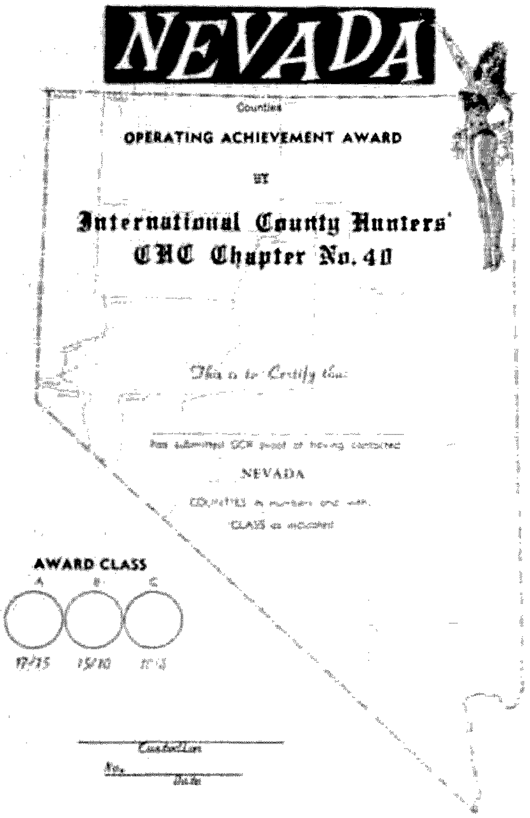
These awards are being issued for a limited time only. Should further information be desired, please contact Awards Manager, Scott R. Douglas, Jr. KB7SB, PO Box 46032, Los Angeles CA 90046, USA.

WORK THE CARIBBEAN AWARD

This basic award is issued for confirmed contact with 20 of the island countries listed below. Endorsement seals are issued

Directory of Certificate and Awards





in increments of 5 countries each. A Gold Seal plaque can be issued for 30 or more confirmations at a cost of $18.95 in US funds or 95 IRCs. SWLs may apply on a heard basis.

Send your verified application and $3.50 or 18 IRCs to the Awards Manager. Do not forward QSL cards because you may have your QSL cards and claimed contacts verified by two amateurs or a local radio club official.

Endorsements will be issued for any mode, band, or power level requested as long as the request is made at the time of initial application. Future endorsements will cost $1.00 US funds plus an SASE.

Forward your application to Scott Douglas KB7SB, PO Box 46032, Los Angeles CA 90046.

Caribbean Country Prefixes

C6, CO/CM, CO4, FG, FS, FM, HH, HI, HKØ (Bajo Nuevo), HKØ (San Andreas), HKØ (Serrana Bank), HRØ, J3/VP2G, J6/VP2L, J7/VP2L, KC4/KP1, KG4, KP4/NP4/WP4, KP4 (Desecheo Island), KP3, KP2/KV4, PJ (Netherland Antilles), PJ (St. Maarten, Saba, St. Eustatius), VP2A, VP2K, VP2E, VP2M, VP2S, VP2V, VP5, VP9, YV (Margarita Island), YVØ (Aves Island), ZF, 6Y, 8P, and 9Y.

WORK THE PACIFIC AWARD

This award should not be mistaken for the famous WAP award which has been offered for years out of New Zealand. This particular award featured this month is sponsored by the Certificate Hunters Club (CHC) and its Manager, Scott Douglas KB7SB.

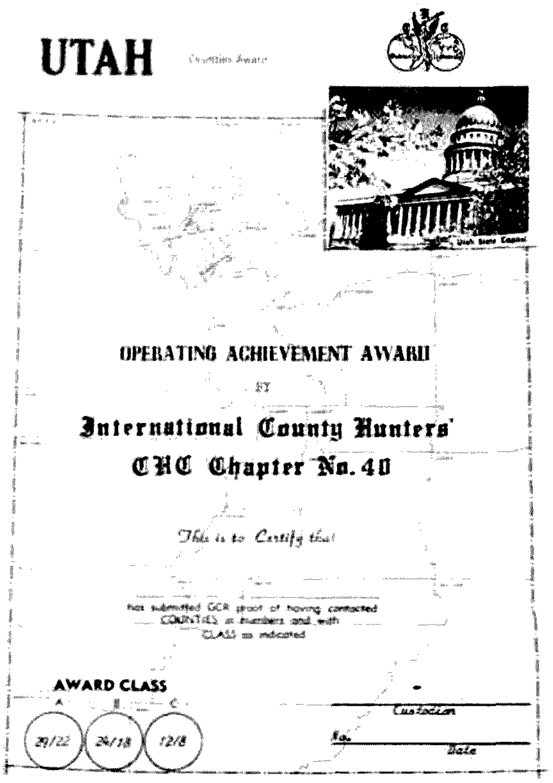
The basic Worked All Pacific Award is issued for 30 confirmed country contacts and is available to any licensed amateur operator or shortwave listener. Endorsement seals are offered in increments of 5 countries. A Gold Seal Plaque can be issued for 50 or more countries worked in the Pacific region if desired. Cost of the plaque will be $16 US dollars or 95 IRCs.

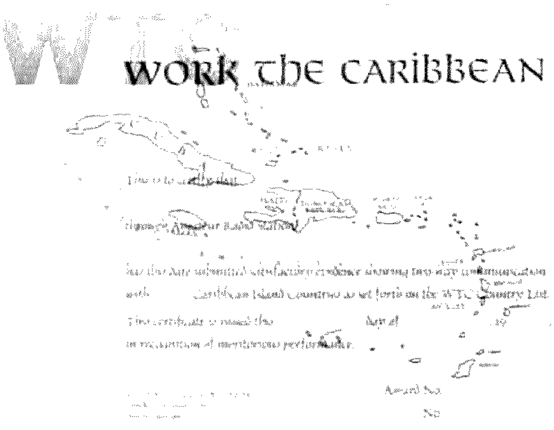
Endorsements for any band, mode, or power will be recognized if such recognition is requested at the time of application.

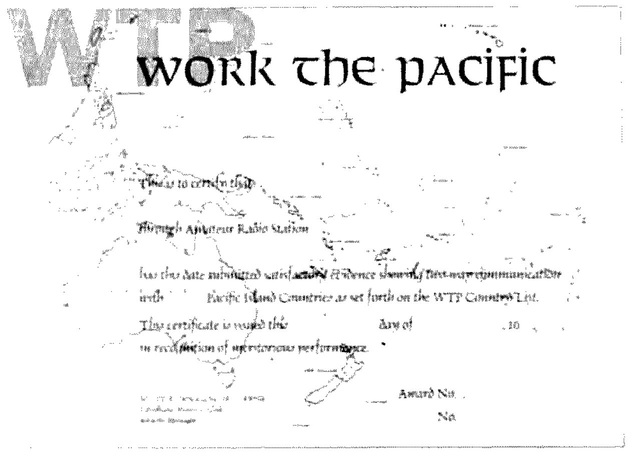
To apply, have your list of confirmed contacts verified by at least two amateurs and have it sent with $3.50 in US funds or 18 IRCs to the Awards Manager, Scott Doulgas KB7SB, PO Box 46032, Los Angeles CA 90046.

Pacific Country Prefixes

A3, BV, C2, CEØA, CEØX, CEØZ, DU, FK, FO (Clipperton), FO (French Polynesia), FW, H44/VR4, HC8, HKØ (Malpelo Island), JD1/KA1 (Minami Tori-







shima), JD1/KA1 (Ogasawara), KB1/KH1, KC6 (Eastern Caroline Islands), KC6 (Western Caroline Islands), KC6 (Valu), KH2, KH0, KH6, KH7, KH3, KH4, KH5K, KH5, KH8, P2, T2/VR8, T3/VR1 (Central, West, and East Kiribati separately), TI9, VK7, VK, VK2, VK9 (Willis), VK9 (Christmas), VK9 (Cocos Keeling), VK9 (Mellish), VK9 (Norfolk), VK0 (Heard), VK0 (Macquarie), VR6, VS5, XF4, BY/YC, YJ, ZK1 (North Cook), ZK1 (South Cook), ZK2, ZL, ZL (Auckland Island), ZL (Campbell), ZL (Chatham), ZL (Kermadec), ZM7, 3D2 and 5W, 9M2, and 9M6.

SPRUCE KNOB

The Parkersburg Amateur Radio Klub of West Virginia will be holding an in-state DXpedition from the top of Spruce Knob, West Virginia. Spruce Knob is the highest mountain point in West Virginia. Elevation is 4862' and it is located in Randolph county, for you county hunters.

The expedition will be on October 3 and 4, starting at 1500 universal time. Station call will be N8CDD. Planned frequencies are: ±3.935, 7.235, 14.335, 21.360, and 28.535; on 2 meters: 144.200, 144.190, SSB, 144.110, CW; on 6 meters: frequencies are 52.150, SSB, 52.525, FM; for CW on HF bands, 10 kHz up on all Novice bands. For special QSL, send an SASE to N8CDD, 902 23rd Street, Vienna W VA 26105.

POPULATION CENTER

The population center of the US as determined by the 1980 census will be commemorated by special event station KA0IAR from 1700 GMT October 10 until 1700 GMT October 11, by the Jefferson County ARC in DeSoto, Missouri. Approximate frequencies used will be 25 kHz up from bottom edge of the General portions of 10, 15, 20, and 40, as well as the center of the Novice portions. For a certificate, send QSL and a large SASE to KA0IAR, 3009 High Ridge Blvd., High Ridge MO 63049.

SUNBELT EXPOSITION

The Colquitt County Ham Radio Society will be operating club station WD4KOW from the site of the fourth annual Sunbelt Agricultural Exposition on October 13-15, 1981. The hours of operation will be 0900 to 1600 EDST each day.

This annual Sunbelt Expo is held each year at Spence Field Air Base, located near Moultrie, Georgia, and is the largest agricultural show in the South. This event draws over 200,000 visitors from all over the United States and foreign countries.

Operations will be mostly on 40 and 20 meters around 7.250 and 14.300 MHz, with some operations in the other HF bands. The members also will be listening for visiting hams on the local repeater, 146.19/.79. Visiting hams are invited to visit the amateur booth at the Expo and operate the station.

A special QSL card is available for those making contact during this event. Contact Joel Goings AA4P, Secretary, Colquitt County Ham Radio Society, PO Box 813, Moultrie GA 31768, for more information.

SOCIAL EVENTS

HOUSTON TX
OCT 2-4

The Houston ComVention 81 will be held on October 2-4, 1981, at the Astrodomain, Houston TX. Features will include an indoor flea market, a Friday night equipment auction, computer exhibits and forums, technical sessions, and DX/Contest meetings with Father Moran 9N1MM. Family activites are planned and the ladies will have a full schedule. Registration is $7.00, the banquet is $18.00, the Johnson Space Center tour is $6.00, and flea market spaces are $6.00 each. For full details, contact HHC, Inc., Box 79252, Houston TX 77024, or phone (713)-481-4586.

CLEARWATER FL
OCT 3-4

The Florida Gulf Coast Amateur Radio Council will holds its annual convention in conjunction with the ARRL South Florida Section Convention on October 3-4, 1981, at the Sheraton Sand Key, Clearwater FL. Registration is $4.00 and children under 12 years old will be admitted free. There will be a QCWA-sponsored luncheon at noon on Saturday, a poolside luau Saturday night, and a fashion show and luncheon on Sunday. Swap tables are $10.00 for the weekend, luncheon tickets are $6.00, and luau tickets are $12.00. Features will include forums, demonstrations, meetings, exhibits for the amateur as well as for XYLs, and a limited swap area. Talk-in on 146.37/.97. For further information or reservations, write FGCARC, PO Box 157, Clearwater FL 33517, or phone Jan KA4ELA at (813)-544-6734.

ROCK HILL SC
OCT 4

The York County Amateur Radio Society will hold its 30th annual hamfest on Sunday, October 4, 1981, at Joslin Park in Rock Hill SC. For additional information and pre-registration, write YCARS, PO Box 4141 CRS, Rock Hill SC 29730.

REVERE MA
OCT 4

The 19-79 Repeater Association of Chelsea MA will hold its annual flea market on Sunday, October 4, 1981, from 11:00 am to 4:00 pm (sellers will be admitted at 10:00 am) at the Beachmont VFW Post, 150 Bennington Street, Revere MA. Admission is $1.00. Sellers' tables are $6.00 in advance and $8.00 at the door, if still available. Talk-in on .19/.79 and .52. For table reservations, send a check to 19-79 Repeater Association, PO Box 171, Chelsea MA 02150.

YONKERS NY
OCT 4

The Yonkers Amateur Radio Club will hold its electronics flea market on Sunday, October 4, 9:00 am to 4:00 pm, at the parking lots of Loral Electronics on Fullerton Avenue in Yonkers, NY. Activities include prizes, an auction, and live demonstrations of computers, satellite TV, hi-fi equipment, and more. Admission is $2.00; sellers' space is $5.00 (bring your own tables). Talk-in on 146.865, 146.910, and CB channel 4. For advanced registration, contact Otto Supliski WB2SLQ, 52 Hayward Street, Yonkers NY 10704. For more info, call (914)-969-1053.

ROME GA
OCT 4

The Coosa Valley Amateur Radio Club will host the annual Rome, Georgia, Hamfest on Sunday, October 4, 1981, at the Rome Fairgrounds. Gates open at 7:00 am, with the main prize drawing at 3:00 pm. Admission is $1.00 and additional prize tickets will be available. Activities include dealer displays, boneyard and flea market, ladies' bingo, and hot, homemade barbeque and Brunswick stew. Top prizes are an Icom IC-260A 2-meter SSB/FM/CW mobile transceiver, an IC-2A 2-meter handie-talkie, and a Trionix full-range frequency counter. You do not have to be present to win the first prize. There will be hourly door-prize drawings plus prizes for the ladies and children. Talk-in on 147.30/.90. For more information, call Cathy Strickland WA4YSV at (404)-235-2311.

SCOTTSDALE AZ
OCT 9-11

The Scottsdale Amateur Radio Club will hold the 1981 Southwestern Division ARRL Regional Convention on October 9-11, 1981, in Scottsdale AZ. There will be major exhibitors and thousands of dollars in prizes. On Saturday, October 10th, a western-style steak dinner will be served and Senator Barry M. Goldwater K7UGA will be the special dinner speaker. Tours of the Senator's "shack" will be conducted also on Saturday. For more information, contact SARC Convention Committee, PO Box 3073, Scottsdale AZ 85257.

MEMPHIS TN
OCT 10-11

The Mid-South Amateur Radio Association, the Memphis VHF Club, the Raleigh ARA, and the Delta ARC will hold the Memphis Hamfest on October 10-11, 1981, in the Youth Building at the Memphis Fairgrounds, Memphis TN. Admission is $3.00 and children under 14 will be admitted free. The hours will be from 8:00 am to 4:00 pm on Saturday and 8:00 am to 2:30 pm on Sunday. Features will include a large indoor and outdoor flea market, on-site trailer hookups, ladies' activities, many forums, and (on Saturday night) a party/dance with snacks. Deadline for Friday night setups for dealers and the flea market is 9:00 pm. Talk-in on .34/.94 and .52. For advance reservations and further details, write Memphis Hamfest, 28 North Cooper, Memphis TN 38104, or phone Clayton Elam K4FZJ at (901)-274-4418 (days) or (901)-743-6714 (nights), or Howard Smith WD5DVB at (901)-372-9618.

ASHEVILLE NC
OCT 10

The Western Carolina Amateur Radio Society, Inc., will hold its 6th annual Asheville Autumnfest on Saturday, October 10,

1981, at the Asheville Civic Center, Asheville NC. Admission is $3.00 in advance and $3.50 at the door. Featured will be dealers, an ARRL booth, and a McElroy memorial CW competition. Prizes include an HF transceiver, a 2-meter transceiver, and many other prizes and door prizes. Talk-in on .31/.91, .16/.76, and .52. For more information, contact WCARS, Box 1488, Asheville NC 28802.

WAUKESHA WI
OCT 11

The KMRA Hamfest '81 will be held on Sunday, October 11, at the Waukesha Exposition Center, Hwy. FT, Waukesha WI. Tickets are $2.00 in advance; $3.00 at the gate. Talk-in on .52. For more info, or advance tickets, write KMRA Hamfest '81, 315 Morey Street, Waukesha WI 53186.

BEDFORD IN
OCT 11

The Hoosier Hills Ham Club W9QYQ will hold its annual hamfest on Sunday, October 11, 1981, at the Lawrence County 4-H fairgrounds, located just south of Bedford IN. Admission is $3.00. There will be refreshments, a free flea market, vendor displays/sales, free camping, and prizes (including a grand prize of an Azden PCS-3000 and a raffle prize of a TRS-80 Model III 4K L1 computer). Talk-in on 146.13/.73. For advance registrations and further information, contact HHHC, PO Box 891, Bedford IN 47421.

PARAMUS NJ
OCT 11

The Bergen ARA will hold a ham Swap 'n Sell on October 11, 1981, at Bergen Community College, Paramus NJ. Seller's admission is $3.00. There will be tailgating only; bring your own table. There will be thousands of spaces available. Buyers will be admitted free. For more information, contact Jim Greer KK2U, 444 Berkshire Road, Ridgewood NJ 07450, or phone (201)-445-2855.

BALTIMORE MD
OCT 11

The Columbia Amateur Radio Association will hold its 5th annual hamfest at the Howard County Fairgrounds (15 miles west of Baltimore, just off I-70 on Rt. 144, 1 mile west of Rt. 144, 1 mile west of Rt. 32) on Sunday, October 11, 1981, at 8:00 am. Admission is $3.00 and tailgating and tables are $6.00. Food and prizes will be available. Talk-in on 147.735/.135 and 146.52/.52. For table reservations and information, write Dennis Parra, 6955 Spinning Seed, Columbia MD 21045.

BIG RAPIDS MI
OCT 17

The Big Rapids Area Amateur Radio Club will hold a fox hunt on Saturday, October 17, 1981, starting at Hemlock Park in Big Rapids MI. Registration is from 8:00 am to 10:00 am. Hunt starts at 10:00 am sharp, rain or shine, on on 146.64. Families, picnics, trunk-sale horsetraders, welcome. $3.50 registration per carload. Information packets sent to advance registrants. Prizes will be awarded and food will be available. Talk-in on .52. For further information, contact Bruce L. Werner WB8TVD, Box 1073, Big Rapids MI 49307.

KALAMAZOO MI
OCT 17

The 27th annual VHF Conference will be held on Saturday, October 17, 1981, at Kohrman Hall, at Western Michigan University, Kalamazoo MI, from 8:30 am through the awards dinner at 6:30 pm. VHF topics will include Design of Low Noise GaAs FET Preamps, An Overview of Packet Networking, and five others. For more information, write Dr. Glade Wilcox W9UHF, VHF Conference Chairman, Western Michigan University, Kalamazoo MI 49008.

IRWIN PA
OCT 17

The Irwin Area Amateur Radio Association will hold its swap and shop on Saturday, October 17, 1981, at the Circleville VFD, Robbin's Station Road, in Irwin PA, just off US 30, 3 miles west of the Pennsylvania Turnpike (exit 7). There will be plenty of indoor and outdoor space available. Features include a flea market, prizes, vendors, and food. Talk-in on 146.925/.325 and .52. For more information, write

Bill Stash WA3AOQ, 421 Dailey Drive, N. Huntingdon PA 15642.

KENNER LA
OCT 17-18

The Jefferson Amateur Radio Club will hold Amacon '81 on October 17-18, 1981, at the Airport Hilton Inn, 901 Airline Highway, Kenner LA. The FCC will conduct tests for all but the Novice level at Our Lady of Perpetual Help School, 530 Minor Street, Kenner LA starting at noon on Saturday, October 17, 1981. Applicants should bring copies of their licenses to the test. Other features will include an indoor flea market, a full schedule of women's events, and FCC, ARRL, and Army and Navy MARS meetings. Talk-in on 147.69/.09. For more details, call W. D. "Bill" Bushnell, chairman, at (504)-887-5022.

GROTON CT
OCT 24

The SCRAMS and the Tri-City Amateur Radio Clubs of Groton CT will hold an auction on Saturday, October 24, 1981, from 10:00 am to 4:00 pm at St. Mary's Parish Hall, at the intersection of Rtes. 1 and 215, Groton CT. Admission is free. Talk-in on .07/.67 or .34/.94. For further information, write Anne Hibbert WB1GVL, 64 Giant's Neck Road, Niantic CT 06357, or phone (203)-739-4970.

CHATTANOOGA TN
OCT 24-25

Hamfest Chattanooga will be held on October 24-25, 1981, at Chattanooga State Technical Community College, Chattanooga TN. Admission is free. Flea market spaces are $2.00 for one day or $3.00 for both days; prize ticket donations are $1.00 each. Events will include dealer exhibits, a flea market, forums, contests, and ladies' programs. Talk-in on .19/.79 and 3980. For dealer information, write Hamfest Chattanooga, PO Box 3377, Chattanooga TN 37404, or call (404)-398-3358.

NEWARK NJ
OCT 24-25

The second annual NJ Microcomputer Show and Flea Market will be held on Saturday and Sunday, October 24-25, 1981, at the Holiday Inn North, Newark Airport, Exit 14 of the NJ Turnpike. Admission to the flea market is $5.00 for sellers and $3.00 for buyers. Admission to both the flea market and the show is $5.00. Saturday hours are 10:00 am to 5:30 pm and Sunday hours are 10:00 am to 3:00 pm. User groups will meet each day and there will be many microcomputer exhibits indoors. For additional information, contact Ken Gordon W2TGH, 3001 Route 27, Franklin Park NJ 08823, or phone (201)-297-2526.

FRAMINGHAM MA
OCT 25

The Framingham Amateur Radio Association will hold its 6th annual fall flea market on Sunday, October 25, at the Framingham police station drill shed. This is the largest indoor ham flea market in New England! Doors open at 10:00 am (sellers may begin setup at 8:00 am). Admission is $1.00; sellers' cost is $8/table (prior to October 15, $10/table after October 15). Talk-in on .75/.15 and .52 direct. There will be a consignment table (for small items), food, and bargains. For more info, contact Ron Egalka K1YHM, 3 Driscoll Drive, Framingham MA 01701; (617)-877-4520.

MARION OH
OCT 25

The Marion Amateur Radio Club will hold its 7th annual Heart of Ohio Ham Fiesta on Sunday, October 25, 1981, from 0800 to 1600 hours at the Marion County Fairgrounds Coliseum, Marion OH. Featured will be many prizes. Food and a large parking lot will be available. Tickets are $2.00 in advance or $3.00 at the door. Tables are $4.00. Talk-in on 146.52, 147.90/.30, or 223.34/224.94. For additional information, tickets, or tables, contact Paul Kilzer W8GAX, 393 Pole Lane Road, Marion OH 43302.

WHITESTONE NY
OCT 25

The Tu Boro ARC will hold a mini flea market and auction on Sunday, October 25, 1981, from 9:00 am to 4:00 pm at the Odd Fellows Hall, 149-14 14th Avenue, Whitestone NY. Admission is a $1.00 donation. Talk-in on 145.62. For table space and other information, contact either Marty WA2APT at (212)-359-6923, or Ed WB2IBQ at (212)-746-4082 after 7:00 pm.

DORCHESTER ONT CAN
OCT 25

The London Amateur Radio Club will hold its 4th annual Swap 'n Shop flea market on Sunday, October 25, 1981, from 9:00 am to 4:00 pm at Lord Dorchester Secondary School, Dorchester, Ontario. Admission is $2.00 per person with children under 12 admitted free. Tables are $1.00 per table (plus admission) and must be reserved and paid for in advance. Talk-in on 147.78/.18 or 146.52. For additional information, write to Dick Reiber VE3IBV, 417 Regal Drive, London, Ontario N5Y 1J8, Canada.

LEAKY LINES

Dave Mann K2AGZ
3 Daniel Lane
Kinnelon NJ 07405

I have frequently been savaged as a result of my implacable refusal to go along with the fashionable new attitude of detente that has developed between hams and CB operators. Largely inspired by persons who hold both tickets, and aided and abetted by certain business interests in both electronics manufacturing and in the magazine publishing field, this phony and hypocritical fraternalism poses naught but disadvantage for us. We have little to gain, but a great deal to lose.

Why the unnatural alliance? Who needs it?

Don't get me wrong. Our ranks have been strengthened by many who were first exposed to communications as CBers. They worked hard to achieve their qualifications and deserve all the credit in the world, for they had much to overcome. In point of fact, many of these converts to amateur radio came in as a result of their disgust with CB and their realization that nothing could ever change it and make it a viable service; it had been allowed to retrogress for such a long period that it was too far gone. Despite all the best efforts of the few constructive elements within CB ranks, they have *never* been able to "clean up their act." CB remains, almost 25 years after its inception, an undisciplined, rowdy service, incapable of self-policing. And the licensing authority, the FCC, is apparently unwilling and unable to do anything about the mess.

Typical of what's been going on is an incident reported in the press on the 23rd of June. Three fishermen whose boat capsized in rough seas off Fire Island, N.Y., may have lost their lives because chit-chatting CBers weekending there refused to relinquish an emergency channel. A Coast Guard search for the missing men was abandoned after 21 hours. The proprietor of the marina where the ill-fated *Water Rat* had been berthed said, "It was outrageous! They begged the people to get off the channel, but the idiots went right on talking." A Coast Guard officer said that the problem of people chatting on reserved channels occurs all the time on Citizens Band.

This points up the obvious: If it weren't for the long-term failure of the FCC to insist not only upon mere possession of the applicable regulations, but also upon familiarity with their provisions, there would be greater compliance. How can users be expected to follow rules that they are not required to be conversant with? And how can there be any assurance that they know the rules unless they are required to take an examination which tests their knowledge?

At the very least, the license grant should have been contingent upon a grasp of the radio regulations applicable to the particular service.

But since the FCC has not seen fit to impose such obligations as a prerequisite to licensing, then we, as a conscientious group faced with the necessity of preserving the traditional character of amateur radio as a self-policing service, must oppose all measures which would water down "entrance requirements" and make the acquisition of a ham radio license easy.

I happen to believe that those who are in the forefront of all movements toward detente between the two services have but one purpose in mind: to establish easy ways for unqualified persons to acquire the ham license—code-free licenses, etc. And among the more insidious methods of accomplishing such a sinister goal is the constant effort to legitimize CB in the public mind so that the vast majority of the people will no longer regard the two services as distinct and apart. And I do not believe that there is any doubt that this tactic has succeeded, at least partially.

We had a cookout here recently, and one of our friends brought a lady along. During the course of the afternoon, she glanced at my antenna installation and said to me, "My, you must be a ham operator. My son is also a ham . . . his numbers are . . ." And she rattled off one of those Citizens Band callsigns. When I explained that there is a marked difference, her reaction made it abundantly clear that she hadn't any idea that her youngster was not an amateur operator; this was the first she'd heard of it.

I've just learned that Kayla Hale W1EMV/TI5 passed on recently. A former editor of this magazine, Kayla was a very dear friend of long standing and was directly responsible for my association with *73*. A constant member of the 3999 gang, she was highly respected and will be greatly missed by all who knew her.

Mentioning Kayla reminds me that just a few months ago she wrote a letter that was published in the correspondence section in which she complained about deliberate interference during her attempt to resolve a medical emergency. Her husband suddenly took ill, and her efforts to get a phone patch were marred by intentional QRM. I cite this in order to acknowledge that in ham radio we also have our problems and are not free from our own incorrigibles. But I think it is fair to say that such idiots are in the negligible minority and are roundly condemned by the vast majority.

The DX fraternity is divided into two distinct groupings—those who have succeeded in working XZ5A, and those who haven't made contact. Of course there is that little coterie of fortunate persons who are already credited with Burma, and among them there are those who worked Don Miller W9WNV some sixteen years or so ago.

There is great discussion going on concerning the legitimacy of the present operation. Documentation was not issued by the Rangoon government, apparently, but by the State of Kawthoolei. Speculation is running rife and there is great uncertainty about whether the DXCC office in Newington will accept the operation as valid. Those who are holding the QSL are advancing all sorts of arguments in favor of okaying the operation, while those who haven't worked the station tend to express doubts about it. Since I happen to be one of the former, I hope that Newington will accept it as valid.

The problem is that Rangoon seems immovable in its unwillingness to permit amateur activity now and for the foreseeable future. Because of this intransigence, it is impossible to anticipate that there will ever be any operation which might have official sanction of the Burmese central government. Apparently an insurgent group is in control of the State of Kawthoolei, where the present operation is based, and if documents issued by such a provincial government are not going to be deemed valid by the League, there is no chance that anyone who still needs Burma will be able to make it.

But what of the last operation from Burma? Did Don Miller submit documentation? And was such documentation scrutinized carefully in oder to establish validity beyond any question? These are questions that are being asked and deserve answers. Because of repeated irregularities in his various DXpeditions, Miller's operations, though accepted at the time, are now widely suspect. My point is simply that unless Don Miller's Burma operation was properly documented, it is grossly hypocritical for the League to void the legitimacy of the present XZ5A/XZ9A operation. How can DXCC refuse to accept Kawthoolei licensing while it accepts the validity of an operation in which the documentation is widely regarded as spurious?

I think that at the very least, the League should examine the records in order to establish beyond question that the documentation offered by Miller was in order and not fraudulent. I think that the League owes this to the thousands of amateurs all over the world who have exerted their efforts to work the present operation in good faith. Cavalier dismissal on a technical point is acceptable only if the technicality is applied across the board

and with equal weight. Any other course is inequitable and fosters some of us an unfair advantage at the expense of the rest. An advantage, I might add, that can never be overcome as long as the present Rangoon government maintains its adamant opposition toward any and all amateur radio activity. That, I submit, is the intention of the Burmese authorities, and for this reason an examination of the continued inclusion of Burma on the DXCC countries list now becomes appropriate, in my view.

I would also express the view that if it is found that the Rangoon government is not now in a position of administrative control of the State of Kawthoolei, and if it can be shown that all civil, military, political, and economic administrative rule is in the hands of a provincial government, then the ARRL should accept radio licensing documentation issued by Kawthoolei as valid and legitimate.

After all, at the time of the writing of our own Declaration of Independence, our colonies had not yet won their freedom from Britain, yet that document's legitimacy and validity has never been regarded questionable; indeed, it represents a milestone in the fight for human freedom and dignity. We have recognized and continue currently to recognize the validity of insurgent governments which succeed in overthrowing despotic, tyrannical regimes throughout the world. Why should Kawthoolei be an exception? Or, more important still, is it the function of DXCC to grant or withhold recognition when there is a *de facto* government in actual power and control? These are not questions which should be decided arbitrarily by a single individual or group acting on the basis of private initiative.

The major problem is that it is the central government in Rangoon which is the main culprit. It is in Rangoon that the small oligarchy wields the oppressive power which denies our Burmese colleagues the right to operate their stations. In the very act of recognizing the validity of the Kawthoolei documentation, we can demonstrate a strong endorsement of our national commitment to human rights, and at the same time we can reinforce our solidarity with our ham colleagues all over the globe. If we deny the validity of the Kawthoolei operation, we serve notice to restrictive governments that they can limit or outlaw amateur radio without running the risk of the slightest objection.

DX CONTESTS

In the months of October and November we have the major contest, what we can call the Olympics of amateur radio: the CQ WW DX Contest. It is unquestionably the biggest and best attended contest of them all. The contesters know what to do; they are trying to get the most contacts with the maximum possible number of countries and zones as possible. The DXers usually show up and tune the bands to find the juicy ones or those that they are still missing on their "most-wanted" lists, because there is an opportunity to work something like 150 countries on the weekend.

A number of Contestpeditions show up from the rare spots. For them, this is a clear advantage, because they have a chance to operate from a good geographical location with good propagation, usually around the equator, and possibly from a country that is relatively rare. The more rare the country, the better the chance to get more people to call them and make more contacts.

To illustrate some of the rates achieved in the contest, the VP2KC operator had runs of about 340 QSOs an hour working JAs. Some stations work around 150 countries on the higher bands. So, wouldn't it be easier to work that BY or ZA under circumstances like that?

Where do the lists stand? Down in the mud. So, all in all, it is a great opportunity to improve your operating skills and also watch those big guns to see how they operate. Also, when you have a big gun locally, you can compare what he is hearing and what you are. Maybe you will discover that that antenna can be better (and bigger) than it is.

It is becoming more common to have some "spectators," that is, operators tuning around the contest turmoil and observing the propagation, signals, techniques, etc. One thing that they also do is give a call to a contester or DXer and help him with a point or two. It is a nice gesture, especially to those who are sitting in the not-so-rare countries such as W or VE. Maybe he was the one who gave you that Spratley or Market Reef contact. So, say thank you.

The multi-multi stations are like beacons on the band. They even call when the bands are seemingly dead, because they are stuck on that band anyway. Some interesting things can be observed.

So, all in all, it is a great opportunity to get that rare one, especially for those who are starting up and need to get there quickly. Watch out for the QSL routes—most of the operations have a QSL manager.

QSLING

What is a QSL card? It is a confirmation of an established contact and it is proof and a record of that event (or, better to say, it is supposed to be). There are always the good and bad, and we have that in our hobby, too. Some DXers figured why bother working the guy if they can maybe get that card anyway, or they would do anything to get the card so they can add it to their total and eventually show up on the Honor Roll. Makes one wonder what honor is if the only desire and drive behind all of this is to get a card, even if the game must be played dirty.

There is a bit of that going on. This was the reason why some DXers were disgusted and tried to get something done about it. Apparently, the ARRL wouldn't do much about it so *they* decided to do something. What they did? QSL scam! Remember Abscam? Similar thing. They went ahead and printed copies of many rare QSL cards and made them available to those who wanted them. You would think that those who wanted to get on the Honor Roll would not go for it? Well, some did. It is best described in the letter by Dave Gardner K6LPL, well-known DXer and DXpeditioner. This letter was sent to *The DX Bulletin*, which broke the news on the whole affair. Here it is:

Approximately one year ago, a group of fourteen amateur radio operators both in the western United States and in Europe involving six countries got together and were discussing the sorry state into which DXing has fallen. It seemed to the group that the original purpose of DXing, the spreading of international goodwill and fellowship, etc., had degenerated into a new form of the hobby which we called "QSLing." At that time, our group, which includes ten members of the Honor Roll, attempted to figure out a way to make an impact on amateur radio, the ARRL, and DXing in general.

Our group has never been anti-League or anti-DXCC. What we are against is QSLing at any price, lack of concern for others, and the virtual disintegration of the generally good-natured camaraderie and willingness to help others that had characterized DXing in the past. The characteristics of DXing have become greed, avarice, and unconcern for others in search of the almighty QSL. Witness the plight of the poor, rare DX operator who gets on the air, and is totally smothered by stations in quest of the almighty QSL. This forces stations to resort to lists so that the poor guy can make a contact. This phenomenon has spread

throughout the world and is not just an American problem, as witnessed by the problems that the most polite of amateurs, the Japanese, had in the demonstration two years ago in China.

It was unbelievable to us how many "straight" amateurs accepted blank QSL cards and submitted them to the League. This is only the tip of the iceberg, as it is a well-known fact that working stations for friends while they are out of town or unable to work rare DX, and even phone-patching those stations through has become a commonplace, everyday habit.

No QSLs were sent out by our group for contacts during this sunspot cycle. Many members of our group have gone on numerous DXpeditions and it was decided that all of our respective QSL managers would be kept completely in the dark about this so as not to endanger their fine reputations. As far as we are concerned, this "operation" is over as we feel we have made our point. No further distribution of cards will be coming from our group. We estimate that between twenty and twenty-five thousand *[emphasis added] QSL cards have been sent and accepted by amateurs throughout the world in every continent except Antarctica.*

We must stop this insane QSL chasing and go back to DXing for the sake of DXing and not just for the sake of a QSL card.
David G. Gardner, M.D. K6LPL

As a result of this, a number of DXers were already disqualified. I think it would be only fair in order to preserve the credibility of the DXCC and the Honor Roll to ask those who are on it or fall in the time frame of the QSL scam to submit their cards for verification. It may be a lot of work, but perhaps there might be some volunteers that can help.

Another questionable way of obtaining QSLs is the operation list. Quite often, the two stations do not hear each other and the report and callsigns get passed by a "third party," the net control. This is definitely not the way to do it and you should stay away from it as much as you can. Don't forget: The whole world is listening and they hear you. What would they think about you? Stay clean! Back in the old country, they used to say that honor is worth more than anything else.

HOW TO QSL?

Generally, I would say QSL to those that you really need. There are some types that QSL anything that moves. For example, you work him in the contest three times on the same band, and you get three QSL cards. You probably already have about ten of them in your collection. This is just an unnecessary burden for the post office, your QSL bureau, your friend, and your pocket, too.

The best thing to do is to keep some kind of records. This is usually done when you are brand new and eager to get a QSL card for each contact you made. I used to have a very nice tracking system, with a book, divided by countries. I used different colors for different bands and modes and then an overall table showing which country was worked, confirmed, and on what band and mode. So, you always know where you stand. Then I gave up after over 40,000 contacts were made; it is just impossible to do that and have the time to operate. The contest logs are nuisance enough.

It is also advisable to keep a record of cards sent out directly and to which QSL manager, so you can try again if for some reason you don't get a reply. As they say: The QSL is the final courtesy of the QSO. It is polite to answer all the requests for your cards. There is no legal right to obtain a card; you can't sue anyone because he did not send you one. You can feel miserable about him, and perhaps "won't hear" him when you fire up from China, but that is about it.

I have experienced a number of threatening letters with exclamation marks just because a guy did not get his card within 24 hours. Well, sometimes there might be reasons for a delay: Cards are not printed, logs are not in the hands of the QSL manager, the boat is going there only once a year, etc.

The contesters are sometimes in a special situation. Usually, the typical multi-multi station can easily make 10,000 contacts on a weekend and this happens about 4 to 6 times a year. It is difficult to QSL everyone contacted. Gentlemen will at least answer all requests. It might take a little longer, but they usually do. This is where those younger and eager hams can perhaps offer to help a contester by volunteering his QSL services. It will give them a chance to get involved in a super-station, learn something, and be of help to many others.

Generally we can divide the QSL types into three groups: regular, rare, and special.

Regulars would be the ones that are around a lot and if you did not get this one to reply, there is always another one. Those we usually QSL via the bureau. Don't waste your money on postage. Put them in a bundle, nicely sorted in alphabetical order by countries and prefixes, and send them to your QSL bureau. Then wait (and wait), especially if it is Box 88, Moscow. Things are slow there. Find out what your local bureau situation is. The ARRL now is running the QSL bureau for outgoing cards. See *QST* for details. Incoming cards are going through the ARRL and local call area volunteers.

It is necessary to have a sufficient number of SASEs with them. Otherwise, cards will be destroyed after a certain period of time. Most of the other countries have their QSL bureaus run by their national amateur radio organizations and they handle all incoming and outgoing cards. Caution: Some hams are not members of the organizations and the bureau is not handling cards for them—cards usually get returned.

It is safe to say that for all the eastern European countries, the bureau is the safe and sure way of getting the cards. When there is a big bundle of cards to be sent out to, let's say, Japan, you will probably be better off to send directly to Japan rather than through your bureau. The cost difference will be small and they can go via slow boat rather than airmail.

Rare ones are those who are rare: There is maybe only one ham in the country, the activity is very sporadic, or the mail service occurs only once a year (like ZD7 or VE with all the postal strikes, hi). Then it is worth it to find out what the best QSL route is. Many times the rare ones have a QSL manager, and if it is a good one, it is easy to get the card. You send the card directly to him. Just remember, he is probably handling over 50,000 cards a year (W3HNK), so make the job easy for him. Make sure that you include an SASE, with the correct postage affixed.

Remember, Canada is not a part of the US and, therefore, it has its own stamps; don't put US stamps on the envelope. If you are desperate, maybe include unglued stamps. They can be used by the manager for his SASEs. But the best thing to do is always to use the stamps of the country that the manager is in, and the correct amount. If you don't have them or cannot obtain them (some philatelic stores have unused stamps of almost all countries in the world), then use IRC coupons. Those are the coupons that you can obtain at your local post office. So, it is a good idea to drop a note to him and ask how many and how much.

One IRC is usually worth the postage of one unit of postal weight in the country at regular, surface mail. Air mail is more and the *Callbook* lists some of the rates to various countries. Usually, three IRCs are sufficient for airmail from most of the countries.

Some countries (most of east Europeans) have 100% censorship at their post offices, so be careful what you are writing so you do not put a ham in jail. Remember, not all countries have the freedom that we in the West enjoy. Some of them prohibit foreign currency and it simply gets removed and put in the State fund. Box 88 apparently even removes the IRCs. Some countries are looking for callsigns on the envelopes and that tells them that there is meat in the envelope—they take it. Or, sometimes there is an unscrupulous postmaster who does that. So, generally, even if you are proud of your callsign, it is better not to put it on envelopes, especially those going to the East or to Africa. This is why the QSL managers are doing their thankless job and serving DXers.

Always make sure that all the information on the QSL card is correct and spend some time doing that. A manager might have lots of work to do with your sloppy card if you did not put your time, date, or band correctly on the card. Remember, he might have 340 QSOs for *one hour* in his log and he has,

perhaps, *5000 QSOs on one band* from that contest station. Double-check your info, and don't make him search through 10,000 QSOs for that *one* you made. Make sure that your date and time are always in GMT (or UTC, as they call it now). Your QSL card is like your picture, so try to look nice.

Special ones would be all those who are either extremely rare or very difficult to get cards from; it is advisable to find out the QSL info right away. This happens when an amateur is assigned to work there or is passing by the country and is active for a very short period of time. A number of DXpeditions fall here, too. You must QSL as soon as possible, before the logs get lost, the QSL manager gives up, etc. Excellent help is provided in the various bulletins and QSL manager lists. To mention two, there is the very sizable W6GO/K6HHD list (Box 700, Rio Linda CA 95673) and the *QSL Report* by QSL Management Association, c/o JH1HWN. Those have the latest, up-to-date information in them, usually taken from the DX bulletins and nicely sorted out and summarized. There is, of course, the *Callbook*, which lists all the hams in the world, and it is almost a must for those who are just starting their QSLing.

I hope that this will shed some light on the art of QSLing. It is always advisable to consult your local big gun if you are not sure. Good luck and may your returns be 100%.

DX NEWS

XZ Burma is getting better and better. Apparently, the station was improved by the installation of a beam and amplifier and operators are starting to work on their own, without the lists. QSL via JA8BMK for XZ5A and XZ9A.

HH0N Navassa operation by a number of operators from Haiti. Operators are trying to do their best and, apparently, Haiti is claiming the island. If Navassa is part of Haiti, then most likely it will lose its separate country status. QSL via WD4JNS.

YO0WUG and other calls with the YO0 prefix are being used to commemorate the world University Games, or Universiade as it is also known.

9Q5VT Zaire is quite active by Len and also shortly by W5VR. QSL via W5VR.

KH6IJ is recovering nicely from his stroke. Worked him recently on CW and he still has a problem with coordination, but it is great to hear that famous call on the air again. One of world's best operators ever. Speedy recovery, Katashi.

Africa. A number of expeditions are wandering around; watch out for the announcements. Most of them are very sporadic, waiting for the licenses.

A7XE operating around 21025, QSL via DF4NW.

AX Australia. Special prefix was used for Prince Charles' wedding commemoration. AX9NL was quite active. QSL cards to their respective VK callsigns.

HAM HELP

I need any info on a Packard Bell oscilloscope, model 5mc CP— schematic, manual, etc. I will pay copying and postage or will copy and return original. Thanks.

Harl Goodsell W7LTH
70 S. 2nd East
Hyrum UT 84319

I need a March, 1975, issue of *73 Magazine*. I also need help in obtaining a Hewlett-Packard HP-46 with the optional LED display and a Fisher HC-10 stereo reverberator.

Ham Help is my last resort in attempting to find these items.

Please send information you may have toward my obtaining these items.

George E. Weinbender
PO Box 747
Lake Havasu City AZ 86403

I would like to correspond with anyone who has converted the ARC-21 or ARC-65 surplus rigs. I have the ARC-65 tech manual and an extra control head.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

CALIFORNIA QSO PARTY

Starts: 1800 GMT October 3
Ends: 2359 GMT October 4

This event is sponsored by the Northern California Contest Club, with strong efforts being made to have all 58 counties in California on for the contest duration.

Single-operator stations may operate only 24 hours of the contest period; off-times must be clearly marked in the log. Multi-operator stations may operate the full 30 hours. Stations may be worked only once per mode per band. All contacts must be simplex. All CW contacts must be made in the CW subband. California stations that change counties are considered to be new stations and may be contacted again for points credit.

EXCHANGE:

California stations send QSO number and county. Others send QSO number and state, province, or ARRL country.

FREQUENCIES:

Novice—3725, 7125, 21125, 28125.
CW—1805, 3560, 7060, 14060, 21060, 28060.
SSB—1815, 3895, 7230, 14280, 21355, 28560.
Try CW on the half hour and 16 meters at 0500.

SCORING:

Each completed phone contact is worth 2 QSO points. Each completed CW contact is worth 3 QSO points. For multiplier, California stations use the number of states, VO/VE 1-7, and VY1/VE8, for a possible of 58. Others use the number of California counties worked for a possible total of 58. The final score is the number of QSO points multiplied by the total number of multipliers.

AWARDS:

Certificates for highest-scoring station in each California county, each state/province, and each country. Trophies to the highest-scoring out-of-state single-op, highest-scoring California single-op, and highest-scoring DXpedition to a California county.

ENTRIES:

All logs and summary sheets must be sent by November 1st to: NCCC, c/o Dennis Egan N6QW, 811 Byerley Avenue, San Jose CA 95125. Please include an SASE with your entry.

NINE-LAND QSO PARTY

Starts: 1800 GMT October 10
Ends: 2359 GMT October 11

A maximum of 24 hours of the 30-hour period may be worked. The same station may be worked once per band and mode. If any stations change counties, they may be worked again.

EXCHANGE:

Nine-land stations send RS(T), county, and state. Others send RS(T) and state, province, or ARRL country.

FREQUENCIES:

Novice—3725, 7125, 21125, 28125.
SSB—1815, 3895, 7230, 14280, 21355, 28600, plus VHF.
CW—1805, 3560, 7060, 14060, 21060, 28060, plus VHF.

SCORING:

Each QSO is worth 2 points. Nine-land stations compute final score as: total QSO points times the total number of states, provinces, ARRL countries, and nine-land counties. Others multiply QSO points by total number of nine-land counties.

AWARDS:

Certificate to top score in each state, province, and ARRL country; 2nd and 3rd places if justified. Also, awards for top mobile, portable, multi-single, multi-multi, club, and Novice.

ENTRIES:

Submit summary sheet and log. Each new multiplier shall be clearly indicated. Send logs and a large SASE to III Wind Contesters, c/o John W. Sikora WB9IWN, 8747 Northcote, Munster IN 46321.

JAMBOREE ON-THE-AIR

Starts: 0001 GMT October 17
Ends: 2400 GMT October 18

It's Jamboree time again! Time for Scouts, former Scouts, and anyone interested to meet on-the-air for a weekend of good Scout talk. It gives amateurs and Scouts worldwide a chance to listen to or talk with other scouts and in some cases where

Final results to be published in November or December 73.

equipment is available for slow-scan television, to see them, also. By the way, this also includes Girl Scouts, Guides, and all Scout leaders.

Hams invite Scout groups to their shacks for the occasion, or Scouts seek out hams. Amateur radio clubs have lists of their members, and a list of such clubs is available from the ARRL, Attn: Sally O'Dell, Director Youth Activities, 225 Main Street, Newington CT 06111. Send an SASE with your request. Hams may contact local Scout offices for names of Scout leaders in their neighborhoods. Look for stations operating at camporees and other Scout events, K2BSA, the national headquarters amateur radio club station, and HB9S, the world Scout Bureau station.

Most operations will occur during the period of 0001 GMT Saturday to 2400 GMT Sunday, but since this is not a contest, operations may start Friday and go into Monday. There is no required contact format, no specific exchange, just Scouting fun. All operations must, however, adhere to FCC rules and regulations.

FREQUENCIES:

Scout frequencies published by the World Bureau are as follows:

Phone—3740, 7090, 7230, 14290, 21360, 28990.

CW—3590, 3750, 7030, 7130, 14070, 21140, 28190.

SSTV and RTTY on usual frequencies.

Since the 3740 and 7090 phone frequencies are outside the USA phone bands, overseas stations using those frequencies may listen inside adjacent USA phone bands or respond to CW calls.

Postcard-size certificates designed by an Australian Scouter and issued by the World Bureau are available from JOTA Coordinator Harry Harchar W2GND, 216 Maxwell Avenue, Hightstown NJ 08520, for anyone participating. Send an SASE with sufficient postage for their return, one ounce per eight cards. They may be requested before the JOTA weekend for distribution then, or for award at Scout Courts of Honor or other meetings.

Logs or lists of participants are not required, but reports of activity and photos are welcome for inclusion in the BSA report to the World Bureau and possible use in Scout publications. Send them to the JOTA Coordinator mentioned above.

QSL OF THE MONTH

This month's winner was submitted by Andy Schaefer N7AST of Hackensack MN and Mesa AZ.

If you would like to enter the contest, put your QSL *in an envelope* and mail it along with your choice of a book from *73*'s Radio Bookshop to *73 Magazine*, Pine Street, Peterborough NH 03458. Attention: QSL of the Month. Entries which do not use an envelope (the Postal Service does occasionally damage cards) and do not specify book choice will not be considered. Sorry.

QRP ARCI CW QSO PARTY

Starts: 1200 GMT October 17
Ends: 2400 GMT October 18

The contest is open to all amateurs and all are eligible for the awards. Stations may be worked once per band for QSO and multiplier credits. Participants must be off the air at least 12 hours in not less than 6-hour periods.

EXCHANGE:

Members—RST, state-province-country, and QRP number. Nonmembers—RST, state-province-country, and power output. Novices and Technicians add /N or /T after the QRP number or power.

SCORING:

Each member QSO counts 5 points regardless of location. Nonmembers' QSOs are 2 points with US and Canadian stations; others are 4 points each. Nonmember Novice and Technician contacts count 3 points. Multipliers are as follows: 4-5 Watts—×2; 3-4 Watts—×4; 2-3 Watts—×6; 1-2 Watts—×8; less than 1 Watt—×10. Stations are eligible for the following bonus multipliers: if 100% natural power (solar, wind, etc.) with no storage, ×2; if 100% battery power, ×1.5. Final score is total QSO points times total number of states-province-countries per band times the power multiplier and times the bonus multiplier (if any).

FREQUENCIES:

1810, 3560, 7040, 14060, 21060, 28060, 50360.
Novice/Tech—3710, 7110, 21110, 28110.
All frequencies plus/minus to clear QRM.
Note: VHF/UHF contacts must be direct—no repeater contacts are allowed.

AWARDS:

Certificates to the highest scoring station in each state, province, or country with 2 or more entries. One certificate to highest-scoring Novice/Technician overall.

LOGS AND ENTRIES:

Send full log data, including full name, address, and bands used, plus work sheet showing details and time(s) off the air. No log copies will be returned. Please indicate if you are a Novice or Technician. All entries desiring results and scores please enclose a business-size envelope with return postage. It is a condition of entry that the decision of the QRP ARCI Contest Chairman is final in case of dispute. Logs must be received by November 20th to qualify. Send all logs and data to: QRP ARCI Contest Chairman William W. Dickerson WA2JOC, 352 Crampton Drive, Monroe MI 48161.

PENNSYVANIA QSO PARTY

1700 GMT October 17 to 0400 GMT October 18
1300 GMT October 18 to 2200 GMT October 18

Sponsored by the Nittany Amateur Radio Club, this is the 24th annual event. Stations may be worked once on each band on each mode. Mobiles may be reworked as they change counties. Repeater contacts do not count.

EXCHANGE:

RS(T), 3-digit sequential serial number, and ARRL section or Pennsylvania county.

FREQUENCIES:

SSB—3980, 7280, 14280, 21380, 28580.
CW—40 kHz up from bottom of CW bands.

SCORING:

Count 1 point for SSB QSOs, 1.5 points for CW QSOs, and 2 points for 80-meter CW QSOs. Pennsylvania stations multiply QSO points by the total number of ARRL sections, plus the total number of Pennsylvania counties, plus a maximum of one DX country. Others multiply QSO points by the total number of Pennsylvania counties worked. Mobiles in Pennsylvania calculate their total for each county and then add these county totals together for the final score.

AWARDS:

Handsome plaques will be awarded to the top Pennsylvania and out-of-state entrants. Certificates for section winners and the 10 top Pennsylvania entrants with a minimum of 10 QSOs. Special club award: An engraved gavel will be awarded to the Pennsylvania club whose members score the highest aggregate scores in the contest.

Be sure to indicate club affiliation on your logs!

ENTRIES:

Dupe sheets are required for entries with 100 QSOs or more. Mail logs, dupe sheets, comments, and an SASE (for results) by November 15th to: Douglas R. Maddox W3HDH, 1187 S. Garner Street, State College PA 16801.

MINNESOTA QSO PARTY

Starts: 1700 GMT October 17
Ends: 2259 GMT October 18

This year's contest is sponsored by a newly-formed club in the Brainerd, Minnesota, area, the Paul Bunyan Wireless Association. There are no mode or time restrictions, but only one transmitter is allowed in operation at one time. No crossband contacts are allowed. Novices compete with Novices, Technicians with other Technicians. Phone and CW are considered the same contest—please score as such. Net QSOs are not valid!

EXCHANGE:

RS(T) and ARRL section/country or Minnesota county.

FREQUENCIES:

Phone—3933, 7233, 14300, 21433, 28633.
CW—3633, 3733, 7033, 7133, 14033, 21033, 21133, 28033, 28133.

SCORING:

Minnesota stations multiply total number of contacts times the number of sections and DX countries. Others multiply number of QSOs by the number of Minnesota counties worked. Score one point for phone QSOs and two points for CW QSOs. Any contact with AD0S counts 10 points per QSO on each band, 80 through 10 meters. If you contact AD0S on 3 or more bands, add 25 points bonus!

ENTRIES:

Logs must include date/time in GMT, bands, modes, and exchanges. Logs must be postmarked no later than November 20th and addressed to: Paul Bunyan Wireless Association, c/o Steven Scott WD0EPE, 801 6th Street North, Staples MN 56479. Include a business-size SASE for returns. Usual disqualification and awards procedures.

1st ANNUAL 40- AND 80-METER PHONE CONTEST

SPONSORS:
73 Magazine, Peterborough, New Hampshire 03458

CONTEST PERIODS:
40-Meter Event—0000Z to 2400Z January 9, 1982
80-Meter Event—0000Z to 2400Z January 10, 1982

MISCELLANEOUS RULES:
Work as many stations as possible on 40- and/or 80-meter phone during the specified times of allowable operation. The same station may be worked once on each band. Crossmode contacts will not count. Single-operator stations may operate a total of 16 hours on each band. All multi-operator stations may operate the entire 24-hour period on each band. Off periods must be noted in your logs and on your summary sheet. Off periods are no less than 30 minutes each.

OPERATOR CLASSES:
(A) Single-operator, single transmitter, phone only
(B) Multi-operator, single transmitter, phone only

ENTRY CATEGORIES:
(1) 40-meter band only
(2) 80-meter band only
(3) 40- and 80-meter bands

EXCHANGE:
Stations within the continental US and Canada transmit an RS report and state, province or territory. All other stations, including Alaska and Hawaii, transmit RS report and DX country.

POINTS:
A station may be worked once on each band. US/VE stations earn 1 QSO point per contact with the 48 states and Canada, 2 points for all others. DX stations (including Alaska and Hawaii) earn 1 QSO point per contact within your own country, 2 points for all others. Contacts made between 1000 and 1400 local time score twice the normal points per contact. Indicate points per contact on your log sheet.

MULTIPLIERS:
1 multiplier point is earned for each US state (48 max.), each Canadian province or territory (12 max.), or each DX country worked on each band.

FINAL SCORE:
Total QSO points times total multiplier points equals claimed score.

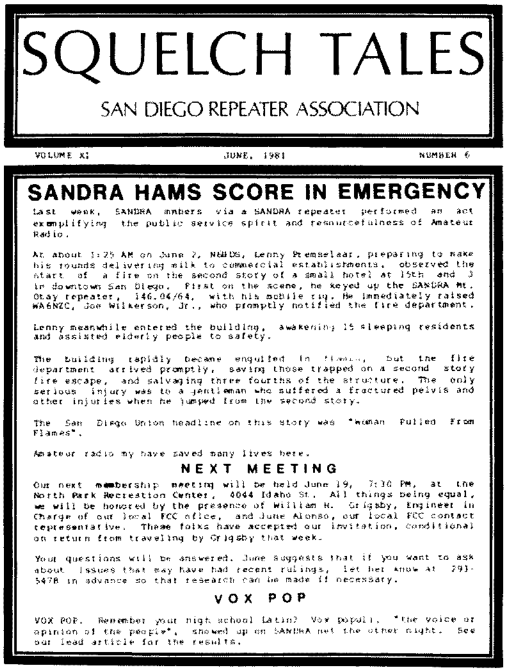
CONTEST ENTRIES:
Each contest entry must include a log for each band in your entry category, a dupe sheet for each band, a contest summary, and a multiplier checklist for each band. We recommend that contestants send for a copy of the contest forms. Enclose an SASE to the contest address listed below.

ENTRY DEADLINE:
All entries must be postmarked no later than February 11, 1982.

DISQUALIFICATIONS:
Omission of any required entry form, operating in excess of legal power, manipulating of contest scores or times to achieve a score advantage, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification.

AWARDS:
Contest awards will be issued in each entry category in each of the continental US states, Canadian provinces and territories, and each DX country represented. A minimum of 5 hours and 50 QSOs must be worked to be eligible for contest awards.

CONTEST ADDRESS:
Send an SASE to: Whidbey Island DX Club
2665 North Busby Road
Oak Harbor, Washington 98277



SQUELCH TALES

SAN DIEGO REPEATER ASSOCIATION

VOLUME XI JUNE, 1981 NUMBER 6

SANDRA HAMS SCORE IN EMERGENCY

Last week, SANDRA members via a SANDRA repeater performed an act exemplifying the public service spirit and resourcefulness of Amateur Radio.

At about 3:25 AM on June 2, N6BDS, Lenny Premselaar, preparing to make his rounds delivering milk to commercial establishments, observed the start of a fire on the second story of a small hotel at 15th and J in downtown San Diego. First on the scene, he keyed up the SANDRA Mt. Otay repeater, 146.04/64, with his mobile rig. He immediately raised WA6NZC, Joe Wilkerson, Jr., who promptly notified the fire department.

Lenny meanwhile entered the building, awakening 15 sleeping residents and assisted elderly people to safety.

The building rapidly became engulfed in flames, but the fire department arrived promptly, saving those trapped on a second story fire escape, and salvaging three fourths of the structure. The only serious injury was to a gentleman who suffered a fractured pelvis and other injuries when he jumped from the second story.

The San Diego Union headline on this story was "Woman Pulled From Flames".

Amateur radio my have saved many lives here.

NEXT MEETING

Our next membership meeting will be held June 19, 7:30 PM, at the North Park Recreation Center, 4044 Idaho St. All things being equal, we will be honored by the presence of William H. Grigsby, Engineer in Charge of our local FCC office, and June Alonso, our local FCC contact representative. These folks have accepted our invitation, conditional on return from traveling by Grigsby that week.

Your questions will be answered. June suggests that if you want to ask about issues that may have had recent rulings, let her know at 291-5478 in advance so that research can be made if necessary.

VOX POP

VOX POP. Remember your high school Latin? Vox populi, "the voice or opinion of the people", showed up on SANDRA net the other night. See our lead article for the results.

NEWSLETTER CONTEST WINNER

Does your club want a newsletter but can't find a way to pay for it? You should consider the approach that is used in *Squelch Tales*, the monthly newsletter of the San Diego Repeater Association. By selling advertising, they are able to meet or exceed the cost of publishing their newsletter. This seems to work well for other clubs, too; about one in three of the club newsletters sent to *73* contains advertising.

The edition of *Squelch Tales* that we selected was 24 pages long—nine of those pages were ads. The club, which has almost 900 members, charges $30 for a full page, $15.00 for a ½ page and $7.50 for a ¼ page or business-card-size ad. Advertisers are encouraged to submit their own layouts and artwork, but the newsletter will also provide assistance free of charge.

Advertising can be a good shot in the arm for a club budget, provided the job is done right. First and foremost, the ads won't sell themselves. The newsletter staff will need to contact prospective advertisers and then *convince* them of the merits of spending money to reach the club's members. Likely candidates include the local ham gear dealer, electronics parts stores, and surplus houses. After all, this is where hams spend their money.

The cost of advertising should reflect the size of your club, the quality of the newsletter, and most important of all, the additional expense that is involved when you run the ad. It

3rd ANNUAL INTERNATIONAL 160-METER PHONE CONTEST

SPONSORS:
73 Magazine, Peterborough, New Hampshire 03458

CONTEST PERIOD:
0000Z January 16, 1982, to 2400Z January 17, 1982

OBJECT:
To work as many stations as possible on 160-meter phone in a maximum of 36 hours of allowable contest time. Multi-operator stations may operate the full 48-hour contest period. Stations may be worked only once!

ENTRY CATEGORIES:
(1) Single operator, single transmitter, phone only (2) Multi-operator, single transmitter, phone only

EXCHANGE:
Stations within the continental US and Canada transmit RS report and state, provinces or territory (i.e., 59 Iowa, 55 Ontario, etc.). All others transmit RS report and DX country.

POINTS:
Five (5) points will be earned for each valid contact with stations in the continental US and Canada. DX contacts outside the continental US and Canada score ten (10) points each. This year for the first time, an additional 5 points *bonus* may be earned for each contact made during the hours of *1000-1400 local time* on either day of the contest.

MULTIPLIERS:
1 multiplier point will be earned for each of the 48 continental states, twelve (12) Canadian provinces/territories, and DX countries outside the continental US and Canada worked during the contest.

FINAL SCORE:
Total QSO points times total multiplier points equals claimed score.

CONTEST ENTRIES:
Each contest entry must include logsheets, dupe sheets for 100 contacts or more, a contest summary sheet and a multiplier check sheet. Please note those contacts made between 1000-1400 local time so you'll be sure to get appropriate contest credit.

ENTRY DEADLINE:
All entries must be postmarked *no later than February 18, 1982.*

DX WINDOW:
Stations are expected to observe the DX window from 1.825-1.830 MHz as mutually agreed by top-band operators. Stations in the US and Canada are asked not to transmit in this 5-kHz segment of the band.

DISQUALIFICATION:
If contestant omits any required entry form, operates in excess of the legal power authorized for his/her given area, manipulates operating times to achieve a score advantage, or fails to omit duplicate contacts which may reduce the overall score more than 2%, disqualification may result.

AWARDS:
Contest awards will be issued in each entry category in each of the continental US states, Canadian provinces/territories, and each DX country. A minimum of 5 hours and 50 QSOs must be worked to be eligible for contest awards.

CONTEST ADDRESS:
To obtain information, entry forms, or to submit a contest entry, forward a *self-addressed stamped envelope* to:

160-Meter Phone Contest
Dan Murphy WA2GZB
Post Office Box 195
Andover NJ 07821 USA

doesn't make much sense to sell an ad for less money than it costs to print and mail.

A good rule of thumb is that the revenue from one page of advertising should pay for two or three pages of the newsletter. For example, a 10-page newsletter that costs $80 to print and mail might have four pages of ads costing $20 each. To keep the readers happy, you can't replace editorial material with ads. Nor can you expect advertisers to pay a small fortune to reach a handful of people.

Advertising alone does not make a good newsletter. *Squelch Tales*, like our earlier winners, has a nice mix of club news, technical tips, and humor. One nice touch is a classified section in which members can list gear. The success of this newsletter is largely the result of a hardworking staff. Editor W6GIC has been associated with the publication for ten years. Her enthusiasm is matched by that of W6UZL who, as a retiree, has plenty of time to gather the news. Rounding out the team is WA6IPW, who uses his background as a printer to ensure that each new edition looks professional yet is reasonable in cost.

If your club is suffering from newsletter blues, perhaps an injection of advertising will help. This revenue, combined with some hard work, will yield a publication that members can look forward to receiving each month. For those of you working on newsletters: Keep up the good work and make sure that your club's publication is being sent to *73*.—N8RK.

HAM HELP

I need manuals or schematic and alignment data on the Knight Star Roamer and the Hallicrafters S-38 "D" receivers. Xerox copies will be OK.

O. L. Sabetto W8ZXG
1717 Burgess Road
Cleveland OH 44112

I am looking for software and equipment compatible with a NorthStar Horizon computer to work RTTY. All help appreciated.

Marc Rubin
16692 Bolero Lane
Huntington Beach CA 92649

I am in need of manuals or any information on the following equipment: Data Engineering, Inc., Space-Matic Electronic keyer; Kyokuto FM 144-10SXRII 2-meter FM synthesized rig; and Ebina Electronics Corp. M7505 10-kHz-30-MHz frequency counter. I will pay for copy or copy and return.

Bob Carson N8CUX
Box 364
Smithfield OH 43948

I would like to get in touch with amateurs interested in Esperanto, the auxiliary language, for the purpose of forming an international ham net.

Saugerties NY 12477

FCC

INQUIRY BEGUN ON SPREAD-SPECTRUM MODULATION IN AMATEUR RADIO SERVICE (DOCKET NO. 81-414)

The Commission has begun an inquiry and rulemaking into whether to allow certain amateur radio users to use spread-spectrum modulation techniques.

In another action, the Commission is exploring the broader area of wideband technologies, including spread spectrum, and said the inquiry/rulemaking involving amateurs would provide the FCC with useful data about the performance of such techniques in the presence of other communications systems.

Wideband modulation techniques differ from conventional modulation schemes—such as amplitude modulation (AM) and frequency modulation (FM)—in that the bandwidth of the transmitted signal is much wider than the bandwidth of the information being sent. Because of the increased bandwidth, such techniques are implicitly prohibited by current rules.

Spread-spectrum techniques were originally developed for military applications concerning covert communications and/or resistance to jamming. The radio frequency signal transmitted in a spread-spectrum system occupies a very large bandwidth, perhaps many megahertz, as compared to the information signal's bandwidth. This wide bandwidth provides for a military signal that is very hard to detect or jam.

The Commission concluded that spread spectrum might offer unique advantages to civilian communications users also. The coding techniques used in spread-spectrum systems, for example, allow message privacy, selective addressing, and code division multiple access (many users simultaneously). These last two advantages provide the user the ability to selectively access only one or a fraction of the total number of receivers sharing the same spectrum. Spreading the signal at the transmitter and collapsing it at the receiver results in a low signal power density and helps the system reject interference. These features suggest the feasibility of overlaying spread spectrum on occupied spectrum, leading to increased spectral efficiency.

In March, the Commission's Private Radio Bureau authorized the Amateur Radio Research and Development Corporation (AMRAD) to conduct limited tests using spread-spectrum modulation. When this special temporary authority expires, AMRAD must submit its findings to the Commission, which will consider them in this proceeding.

Experimenting will be limited to amateur Extra and Advanced class licensees, whose members have been tested in advanced phases of radio electronics. Because spread-spectrum systems are inherently more complex than narrowband systems, the Commission said these licensees were best qualified to build and operate the necessary equipment so as not to interfere with other radio users. (Material covering spread-spectrum techniques will be added to future amateur Extra and Advanced class tests.)

Due to legal and technical considerations, the Commission proposes authorizing spread-spectrum modulation only in the 50-54-MHz, 144-148-MHz, and 220-225-MHz bands. However, it welcomes requests for special temporary authority to perform limited experiments in the amateur bands above 225 MHz.

The Commission will not limit system design, but only proposes that a system's authorized bandwidth be equal to or less than the width of the amateur band the system is operating in and be contained within that band. Although no interference problems are anticipated, local engineers-in-charge will be allowed to require stations transmitting spread-spectrum signals to cease operation, if necessary, to stop interference. Provisions to facilitate monitoring by the Field Operations Bureau and by other amateurs are proposed. Commenters may address the issue of interference potential in overlaying spread spectrum on the three aforementioned bands.

The inquiry notice lists questions that might guide those wishing to comment in this proceeding. Interested persons should obtain a copy of the notice.

Action by the Commission by Notice of Inquiry and Proposed Rulemaking (FCC 81-290). Commissioners Fowler (Chairman), Lee, and Quello, with Commissioner Washburn concurring and issuing a statement. For more information, contact Mike Kennedy at (202)-632-7073.

HAM HELP

Active or retired police amateur radio operators who are members or potential members of the International Police Association interested in forming an IPA Ham Radio Net please contact the Secretary-Treasurer of IPA, U.S. Section, Region 10, at 89 Oakridge Avenue, Nutley NJ 07110.

Suite 718
7046 Hollywood Blvd.
Hollywood CA 90028

HOORAY FOR HOLLYWOOD DEPARTMENT

About a year and a half ago, my friend, Jim Davis KA6IUH, was the program director for Los Angeles radio station KMPC. Thanks to Jim, I had a chance to meet and become friends with a number of darn nice people involved in one way or another with the KMPC operation. Among them is a man named Gary Owens. For many years, Gary was the afternoon mainstay of KMPC, though I suspect he is best known to the rest of the nation as the "announcer," with his hand always to his ear, on the old Rowan and Martin "Laugh In" series. Anyhow, one afternoon while I was visiting Jim in his office, I asked if he minded my asking Gary if he would record some public service announcements about amateur radio. Jim did me one better. He suggested we both ask Gary; we did, and Gary graciously agreed to do them.

That evening, I called Lenore Jensen W6NAZ. Lenore is the ARRL's Los Angeles area public information assistant. She's also directly responsible for 99.9% of all the amateur-radio-related announcements you hear on radio and see on TV. We worked out the details of what the announcements should say, and a week later Gary, Jim, and I recorded the copy onto tape. A few days later, my organization, the Westlink Radio Network, formally donated these recordings to the American Radio Relay League for use in their ongoing campaign to foster public awareness of amateur radio. Since then, they have been heard on radio stations nationwide.

In early July, a plaque thanking Gary for his efforts on behalf of all amateur radio operators was awarded to him by the ARRL through Lloyd Sigmon W6LQ. Having Lloyd be the presenter could not have been more appropriate since he was the man in charge of KMPC when Gary came to the station 19 years ago. Also present at the awards ceremony were Lenore (W6NAZ) and Bob (W6VGQ) Jensen. After thanking Lloyd and the League for the recognition, Gary promised to hook up a code-practice oscillator to the key, and practice a bit of CW with it. No, Gary isn't a ham, at least, not yet. But if he ever decided to take the plunge, he would be a welcome addition to our service.

As the individual who instigated this whole affair, I also would like to express my sincere gratitude to Gary. People in Gary's position are constantly bombarded with requests for similar freebies. I know a number of people who flatly reject any such request for any reason, and I cannot blame them for doing so. Remember, in the case of PSAs such as ours, virtually everything is donated including the talent. The latter is usually the most expensive part of producing a commercial of any sort. There's a Hollywood saying which goes, "Big names cost big bucks," and this is rightly so since for an entertainer or air personality, his or her voice and appearance are their livelihood.

Famed broadcaster Gary Owens (left) receives a Brass Key plaque from Lloyd Sigmon WGLQ, on behalf of the ARRL. (Photo by Bob Jensen W6VGQ.)

What's nice is that a person of Gary's caliber and standing has as high a regard for our hobby service as to donate his talent in the hope that we can grow and prosper. For this, I can only say to him a simple but meaningful, thank you! I also want to thank Jim Davis KA6IUH along with Lenore Jensen W6NAZ. Putting these PSAs together was a team effort and everyone involved deserves a hand.

A SPECIAL REPORT

The following is excerpted and being reprinted from the Spring, 1981, Southern California Repeater Remote Base Association Newsletter. I am bringing you this information for several reasons. First, like all other bands, the 420- through 450-MHz spectrum is facing its own form of crisis in many geographic areas, and herein you will find the details of how one group of dedicated radio amateurs plans to deal with the problems that lie ahead. Second, outside of those who use the band in Southern California, little is known by the outside world. Through this input, it is my hope (and I suspect that of SCRRBA as well) that all amateurs will have a better understanding of the need for ongoing voluntary spectrum management to prevent chaotic conditions from developing within our amateur relay spectrum. The report was prepared by Gordon Schlessinger WA6LBV of SCRRBA's Technical Committee. Due to its length and scope, it will be presented in several parts. First, some background for those of you unfamiliar with the group.

Like all other voluntary spectrum management organizations in California (and perhaps nation wide) the SCRRBA was a child of the original California Amateur Relay Council. From it came such well known regional organizations as the Northern Amateur Relay Council and the Southern California Repeater Association (which in 1978 again split into two "special interest" groups now known as TASMA and 220-SMA). Over the years, this column has followed the political motivation leading to these changes toward regionalization and specialization, so I will not repeat them here. Those interested can find more detail by reading the back issues of *73* from mid-1972 through the present. I also tried to detail some of the history of California frequency coordination in my *Practical Handbook of Amateur Radio FM and Repeaters*, also available from *73*. (Yet another excellent reference is "The Remote Base: An Alternative To Repeaters," authored by Gordon Schlessinger WA6LBV and Bill Kelsey WA6FVC. This article appeared in the April, 1977, issue of *Ham Radio Magazine*. While technical in nature, it did spend time explaining some of the colorful history of UHF-relay communication in this region)

SCRRBA REPORT, PART I

For the Southern California UHF relay community, the future is now. In many respects, the future arrived yesterday. We are big; we are complex, and we have big complex problems to be faced. *Right now.* Whether or not we face them, whether or not we solve them, will entirely determine if we will continue to operate our relay systems in the future as we have in the past. Let there be absolutely no misunderstanding about this: A crisis in frequency coordination is already upon us.

In Southern California, we have developed a phenominal number of UHF relay systems, leading to the virtually complete utilization of the 440-450-MHz region of our 70cm band. This fact alone creates unprecedented difficulties for the Technical Committee both in coordinating channel pairs for new systems and in managing the present array of coordinated relay stations.

UHF Frequency Coodination In Crisis

"We begin with data. In Southern California, the 440-450 portion of the band is entirely used for 'relay station' input and output channels. The 420-431-MHz portion of the band, which previously supported some relay 'main input and output' pairs, has now been devoted entirely to link channels and a co-shared 6-MHz ATV simplex channel. The 431-440-MHz portion is utilized for 'weak signal' DX communications, satelite work, an ATV repeater input channel (output on 1250 MHz), and a few one-way link channels.

"Within the 440-450-MHz portion of the band, three channel pairs are reserved for simplex operation and associated special-purpose activities. This results in a theoretical 197 pairs for mobile relay channels available for coordination.

"At the present time, the Technical Committee frequency coordination data base shows a total of 320 systems coordinated to these 197 pairs, with several additional coordinations performed but not yet included in the latest computer printout. We therefore have, at present, an average of 1.6 coordinated systems per channel pair. Additionally, there is a backlog of applications awaiting coordination, for which supplemental data has been requested and has not yet been received. Finally, we are receiving a relatively constant number of completed applications for new UHF frequency coordinations each month. In the near future, we will exceed an average of 2.0 systems per channel.

"Compounding the channel-loading figures are some secondary considerations. The band was initially coordinated from the 'top down,' with the earliest coordinated systems utilizing output channels in the 448-450-MHz portion of the band. (In this discussion, only the output channel frequencies will be mentioned; the input channels, 5 MHz lower in frequency, are implicitedly included). Many of these early systems tend to be widely utilized, often by individuals who hold cross-membership in other groups as well. Consequently, the top end of the 440-450-MHZ band is already entirely filled. Additionally, one of the ostensible benefits of our Southern California location is also a constraint on the frequency-coordination process. High performance, wide-coverage systems coordinated to our highest mountains, dominate a channel over much of the populated Southern California land area. A channel pair which is in use on Santiago Peak or other mountains cannot easily be co-shared with another system anywhere else in the Southern California coastal region. Thus, to the degree that more and more systems are established on these mountains, the number of channel pairs available to be coordinated elsewhere in Southern California is reduced.

"Under these constraints, the Technical Committee must coordinate new systems onto channels which already contain at least one other operational system somewhere in Southern California. On this basis alone, there are potentially very large problems in UHF frequency coordination looming ahead. But there are additional problems that must be addressed."

Next month, we will cover these and begin to look at possible solutions as outlined by SCRRBA in its Special Report.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randalistown MD 21133

Ah, autumn! The leaves out here in the country are changing to the bright collage of red and gold, and I find myself outside, spraying WD-40 on the kids' swing set to *protect* the pivot from winter's rust. While I am outside, I often hear the familiar rumble of the postman's truck. Let's see what kind of goodies we can turn up in this month's mailbag.

A good starting point is this letter from Frederick C. Wood WB3JKC, here in the Baltimore area, who writes about his attempt to get on RTTY. Fred states that he is "...twelve years of age and a General class license holder." He recently acquired an old Model 19 Teletype® machine, along with an HF transmitter and receiver. A home-brew demodulator provides good receiving copy, but transmitting is his problem.

Fred installed the circuit shown in Fig. 1 in his transmitter, but has the following questions:

1) Where do I connect to from the FSK unit to the Model 19 machine keyboard? I do not have a manual for the Model 19 machine.

2) To obtain the 170-Hz shift, which I will be using for RTTY, simply, what are the adjustment procedures for the trimmer capacitor and the 100k shift pot?

3) Why is the keyboard grounded as indicated?

Fred concludes that he has been unable to find the answers to these questions despite several months of reading, and signs himself a "frustrated 12-year-old." I know that others have found themselves in the same situation as Fred; let's look at the answers to his questions.

To begin with, the Model 19, which is really a Teletype Model 15 with tape equipment, provides the connection for the keyboard on the machine's left side, your right as you look at it, on the "30" terminal block. This screw-terminal block has six terminals on it, numbered 31 through 36, and the keyboard is brought out to 32 and 34.

Now, before you just go and hook the keyer to these terminals, there is one more item you must attend to. On an unmodified Model 15 keyboard, there is a filter, officially dubbed a "9222 Filter," which serves to suppress sparking at the keyboard contacts. Composed of a coil and a few capacitors, this is the last thing you want to put across a shift-pot circuit! The filter is normally wired across the contacts and located above the keyboard contact assembly; remove it.

We move on to your second question, regarding adjustment of the circuit. The variable capacitor is set to provide the correct degree of shift, whereas the potentiometer is used to precisely set the shift. The way I set them up is first to turn the pot to maximum, that is, the higher position above ground. This will provide the maximum shift. Now adjust the capacitor to produce an 850- or 900-Hz shift. From here on, leave the capacitor alone! The pot may be used to back down the shift to 170 Hz, or whatever, without worrying about exceeding the 900-Hz maximum shift. I mounted the pot in a little box on top of the transmitter, with a jack in the back to receive the keyboard line coming from the printer.

Now, about those grounds. Remember that the keyboard must be isolated from the TTY loop. Also, the shift-pot circuit is constructed to work against chassis ground of the transmitter. You see, a ground by any other name is still a wire (or something like that). All those symbols mean is that the "cold" side of the keyboard, pot, and transmitter chassis are all connected together. You don't have to pound an eight-foot copper rod through your shack floor next to the Model 19!

While some are working on machines a score or more years old, others are looking at more modern devices. Such is the subject of a letter received from Robert LeMaster, Sr. WA9NZQ/5 over in Bentonville, Arkansas. Bob writes that he has searched high and wide for video RTTY systems to build that do not use

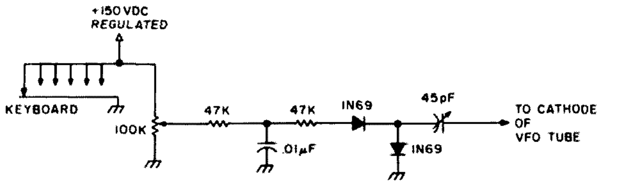

Fig. 1. One version of the "shift-pot" circuit.

a computer. He feels that he has no use for a computer and does not want to buy one just to use on RTTY.

Well, Bob, I'm not going to try to convert you to "computerism" here. We have talked at length in the past about the versatility one gains with a computer on RTTY. If you are interested in a "glass Teletype" only, several have been described in *73* in the past and are listed below:

"Build This Exciting New TVT," *73 Magazine*, March, 1976, p. 76.
"ASCII/Baudot With A Prom," *73 Magazine*, June, 1976, p. 114.
"A RTTY/Computer Display Unit," *73 Magazine*, July, 1976, p. 118.
"The XITEX Video Terminal," *73 Magazine*, December, 1978, p. 132.

I will point out, though, that by using a microprocessor-based system, you can gain a good deal of "smarts."

How about the ability to transmit and receive at several speeds, hold canned output in buffers, like a brag tape, and have the machine clean up your typing; all this is easy with a CPU controlling the station, very hard without it. Now, I am not talking about buying a $1000 system and tying it down to RTTY, nor am I thinking of buying a large system and using it occasionally on the air. An attractive alternative is to put together a small computer, on one board, with the program in permanent memory and a limited amount of on-board read/write memory.

Such a computer is termed a "dedicated" one, and can be put together very inexpensively. For example, a simple 6802-based system was described by Pete Stark in *Kilobaud Microcomputing* last year. The whole system fits on a small PC board. Write Pete at PO Box 209, Mt Kisco NY 10549, for details of the "Kilobaud Klassroom Komputer."

Ah, but you say, what about programming? Watch closely here in *73* and you soon shall see a super program, written for the 6800 (will also run in 6802 without modifications) which provides all the features a RTTY station needs. Requiring less than 4K of memory, it is designed for most 6800 systems using serial terminal interfacing via an ACIA.

Need more help? Scheduled to appear on the horizon very soon is a newly-updated edition of *73*'s *RTTY Handbook*. Containing all new material regarding RTTY equipment, this promises to become a new classic which belongs in every RTTY station. Among the new material will be video RTTY, both with and without a computer, along with new transmitting and receiving circuits, and a few bells and whistles. Watch for the announcement in the Radio Bookshop section of *73*.

Before I close this month, let me acknowledge a letter from Cal Sondgeroth W9ZTK, who writes concerning the program published in this column last July. Cal has taken a razor to the program and honed away sixteen bytes or so to make it more compact. Among his suggestions are to store variables on the 6800's Page 0, to allow direct addressing, and storing the START and STOP bits integral to each data byte. In other words, where I used "10101000" for the numeral "4", Cal would use "00101010." In his version, the bits are, reading from left to right, a "0" START bit, the five data bits ("01010"), a "1" STOP bit, and a "0" DON'T CARE bit. My order includes a "1" CASE bit, five data bits, and two DON'T CARE bits.

That CASE bit is needed to tell the program whether the character about to be sent is FIGS or LTRS, and to prompt the appropriate change of case, if required. I will grant that the one DON'T CARE bit could be used for the same purpose, but it seemed more general to store only the data and plaster the START and STOP bits externally.

The reason I did not use Page 0, by the way, is that this routine is part of a larger program, and most of that page is accounted for by other variables. In the practical system, however, Page 0 makes sense to use. It's just that here, as an example, I chose to use extended addressing.

Some reviews coming up in the next few months. I will try to sprinkle a few letters in here, too, maybe even a surprise or two! All for you, in RTTY Loop.

NEW PRODUCTS

BONE-CONDUCTION HEARING AID

Individuals with hearing impairments may soon be able to enjoy sound-oriented pastimes like ham radio by using a bone-conduction hearing aid developed by Matsushita Electric Co.

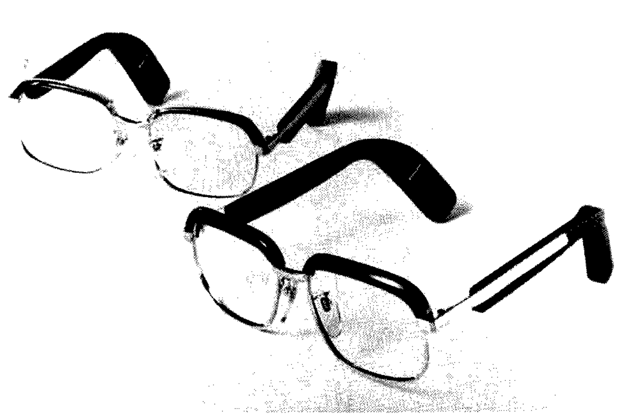
This electronic breakthrough bypasses the eardrum by vibrating the bones near the inner ear. A small microphone, amplifier, battery, and vibrating device are built into the frames of special eyeglasses. Matsushita plans to release this new hearing aid for the US market in the near future.

For more information, contact *Ruder and Finn, Inc., 110 East 59th Street, New York NY 10022.* Reader Service number 481.

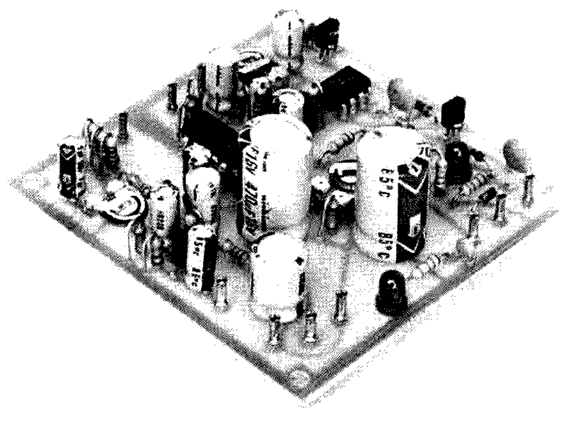
NEW HAMTRONICS® REPEATER MODULES

Hamtronics, Inc., long noted for FM transmitters and receivers commonly used for building repeaters, has now completed their line of repeater modules by offering inexpensive COR and CWID modules.

The 3" x 3" COR module kit contains an electronic relay to actuate the transmitter when the receiver squelch opens. Adjustable tail and time-out timers are provided on the board, as well as an audio mixer to combine the ID tone with the receiver audio for application to the transmitter. Another nice feature is a separate speaker driver amplifier stage which allows a local speaker to be operated completely independent from



Bone-conduction hearing aid from Matsushita.



Hamtronics® COR module.

the repeater audio level setup control, without using hard-to-find L-pads.

The 3" × 7" CWID module kit contains a tone generator controlled by a 158-bit diode matrix. Adjustments on the board control the ID speed, tone, and time. A special output filter eliminates the key clicks found on many repeater IDers. Although many articles have appeared recently on PROM IDers, many still prefer a diode matrix because it can be easily reprogrammed at any time without further expense. The CWID module is constructed on a double-sided PC board with plated-through holes for easy assembly. The CWID and COR modules are designed to be used with Hamtronics® transmitter and receiver modules as well as most other types. For further information, contact *Hamtronics, Inc., 65F Moul Rd., Hilton NY 14468; phone (716)-392-9430.* A complete 1981 catalog, which includes all Hamtronics® FM and SSB equipment, is yours for the asking. (For overseas mailing, please send $2.00 or 5 IRCs.) Reader Service number 477.

BILAL ISOTRON ANTENNAS

Isotron antennas, designed and manufactured by the Bilal Company, employ a unique new embodiment of a full-size harmonic antenna which permits the radio amateur who has limited space to get on the air from an apartment, condominium, mobile home, or other space-limited environments. There are no compromises in matching or tuning Isotron antennas to your transmitter. This unique design allows direct feed with standard coaxial cable and does away with the need for radials.

How is it that an eighty-meter antenna, for example, can be only four feet tall, eighteen inches deep, sixteen inches wide, and weigh a mere eight pounds... yet perform as well as a full-size antenna? Bilal claims that the answer is in research and development. Isotron antennas were five years in development and testing, and now are available in 80-, 40-, and 20-meter models.

For more information, call or write to *Bilal Company, Star Route, Florissant CO 80816; phone (303)-687-3219.* Reader Service number 483.

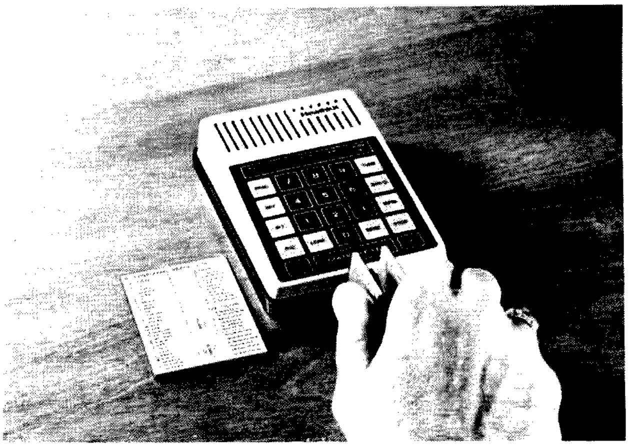
Benjamin Michael Industries' military-time clock.



The Heath μMatic Memory Keyer.

MILITARY-TIME CLOCK

Benjamin Michael Industries, Inc., has announced the addition of the Model 173DM to its line of professional military-time-format clocks.

The 173DM features dual, independent digital clock circuits housed in a solid walnut case. The unit is suitable for placement on any desk, communications console, briefing table, etc. Military time is displayed on the left clock face while standard 12-hour format with AM/PM indicators is used on the right. Each clock is independently set, allowing display of different time zones if desired. This arrangement makes the 173DM ideal for applications requiring the use of both Universal Coordinated Time (Zulu) and local time.

Both large displays are of the LCD type for excellent visibility and ultra-low power consumption. The 173DM features quartz-crystal accuracy and over one year of operation on a single, readily-available battery. The absence of a power cord makes the unit ideal for desk-top use and eliminates the need for resetting after commercial power failure.

For more information, contact *Benjamin Michael Industries, Inc., 65 E. Palatine Road, Prospect Heights IL 60070.* Reader Service number 480.

UNIQUE MICROPHONE SYSTEM

Mobile operating will never be the same! Daiwa's RM-940 brings the total freedom of cordless operation with a lightweight, compact microphone, infrared sensor, and control/charger unit.

The electret condenser microphone can be hung around the neck like a pendant (cord supplied), or conveniently clipped to a shirt pocket. A latching pushbutton switch activates the tiny infrared transmitters on the microphone. Audio and transmit/receive switching are then transferred via infrared beam to a sensor mounted near the sun visor or the rearview mirror. The maximum usable distance is 3.5 feet. An additional sensor can be added for broader coverage.

Infrared microphone system from MCM Communications.

The control/charger unit features Velcro pads for easy mounting and microphone plugs compatible with most Kenwood, Icom, or Yaesu rigs (specify when ordering). Other plugs can be installed to suit particular needs. A maximum of eight hours of charging time will provide a minimum of five hours of continuous use. The control/charger unit also provides a visual (LED) and audible (soft beep) indication whenever the microphone is switched on. Optional microphone wind screens are available. For more information, contact *MCM Communications, 858 E. Congress Park Dr., Centerville OH 45459.* Reader Service number 478.

HEATH'S μMATIC MEMORY KEYER

Reports say a sneak preview of the new Heathkit® SA-5010 μMatic Memory Keyer created much interest at the 1981 Dayton Hamvention. The keyer is now featured in the latest Heathkit Catalog from Heath Company.

Described by a Heath spokesman as compact and modern in styling, the SA-5010 uses a custom microprocessor to provide up to 10 buffers for storing up to 240 characters of text or commands. These variable-length buffers eliminate wasted memory space by letting the user store text in several buffers and then string them together in any sequence. Command strings also can select the speed, weight, spacing, and auto-repeat count for each message so selected. This feature is said to make the μMatic so versatile that Heath has applied for a patent on it.

The SA-5010 employs a 20-position keypad for entries, and features easy-to-use integral capacitive "touch" paddles. A rear panel jack is provided for use of a mechanical paddle, if so desired.

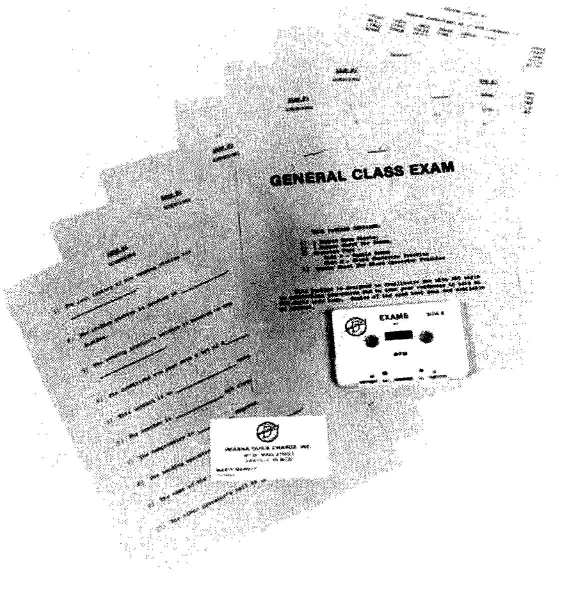
A "practice" mode sends random code groups of random length and selectable types. The 100 different random sequences are repeatable, so the ham can check copy for accuracy. All 100 sequences are altered each time the keyer is turned on, to give a total of 6,400 different practice sessions. Each sequence sends approximately 3,000 characters before repeating. The user can choose any speed between 1 and 99 words per minute, and any of 11 weight settings.

CMOS memory with battery backup is said to retain the buffer contents, as well as the last-selected speed, spacing, weight, and repeat count whenever the keyer is turned off or unplugged.

Built-in diagnostics check the microprocessor each time the keyer is turned on, and also test buffer memory whenever the μMatic Memory Keyer is reset. For the left-handed CW operator, a special two-key function reverses the paddles. The keyer even remembers to turn itself off if the user forgets!

The SA-5010 features built-in sidetone oscillator and speaker with variable pitch and volume controls. Phone jack and ear phone are included for private listening. A plastic case covers the die-cast zinc base, which is weighted to reduce movement during keying. The keyer requires the optional 120 V ac Heathkit PS-5012 power supply. Step-by-step instructions make this a two-evening kit.

The SA-5010 μMatic Memory Keyer and nearly 400 other



The Indiana Quick Charge CW exam package.

build-it-yourself electronic kits are featured in the latest 104-page Heathkit Catalog. For a free copy, write *Heath Company, Dept. 350-115, Benton Harbor MI 49022.* In Canada, write *Heath Company, 1480 Dundas Street E., Mississauga, Ontario L4X 2R7.* Reader Service number 485.

CW EXAM PACKAGE

Indiana Quick Charge, Inc., has recently completed a Morse code practice package for the new-style FCC exams. The package consists of five completion-style exams, two answer sheets, and one cassette tape. The A side of the tape has five segments of text, each approximately five minutes long. The B side has mixed characters practice ranging from a little below the test speed and gradually working up to the speed desired. Each sample test is on a separate sheet, with an answer key for all the included sample tests. The cassette is well produced, with excellent keying characteristics. All the text and mixed characters are computer-generated, assuring evenness and accuracy.

Designed to test the user's readiness to take an FCC code exam, it should be stressed that the text included is composed, and is not a word-for-word copy of any actual FCC tests. It is similar only in style and length, and is intended to test the skill and ability of those who are preparing to take the actual test. Two packages are currently available: the General class practice at 13 words per minute and the Extra class practice at 20 words per minute.

For more information, write: *Indiana Quick Charge, Inc., 367 West Main Street, Danville IN 46122.* Reader Service number 479.

UHF ALL-MODE AMP

The D1010 amplifier is a solid-state all-mode amplifier designed to be used in the 430-to-450-MHz amateur band. It will amplify a 10-Watt signal to more than 100 Watts output; 2 Watts input produces 25 Watts output. The D1010 can be keyed with as little as 300 milliwatts. This makes it a versatile amplifier for all low-power transceivers and HTs. The D1010 is biased as a linear amplifier, therefore, it will amplify FM, SSB, CW, and ATV signals.

Other features include remote operation with the optional RC-1 remote head, external or internal keying circuitry, over-temperature protection, and the typical *rugged* packaging that is a part of all Mirage products.

The D1010 carries a 5-year warranty on all parts except the rf power transistors which are warranted for 1 year.

The D1010 will be an asset for any station, whether on OSCAR, mobile, remote base, or SSB/CW DX.

As with all Mirage products, they are only available through their worldwide dealer network. For further information, contact *Mirage Communications Equipment, Inc., PO Box 1393, Gilroy CA 95020.* Reader Service number 476.

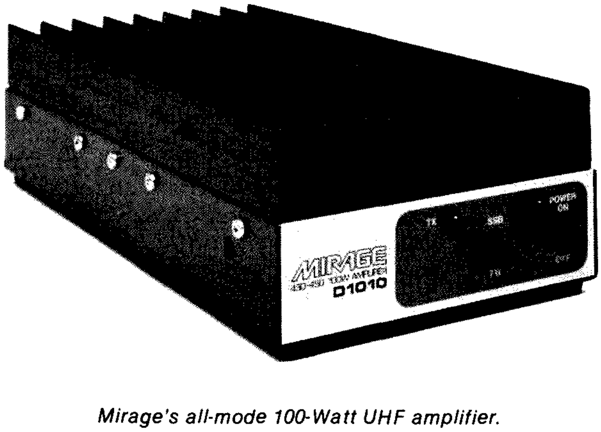
HYBRID COMPONENTS DATA BOOK

A new data book detailing the specifications of discrete semiconductor components has been published by Motorola. The new Discrete Hybrid Components Data Book covers 10 different discreet-product categories, including a variety of transistor, diode, thyristor, and optoelectronic lines, and includes five different packaging methods: standard chips (dice), flip-chips, Micro-T™, SOT-23, and SOT-89.

The book includes an easy-to-use cross-reference between standard discrete packaged devices and equivalent *unencapsulated* chips, and provides both electrical and physical data for each of the chips.

All Hybrid components described in the Data Book are available from Motorola or through authorized Motorla Hybrid Components distributors.

The Motorola Discrete Hybrid Components Data Book is avail-



Mirage's all-mode 100-Watt UHF amplifier.

HANDI-CON V

The Handi-Con V (HC-V) is a self-contained VHF-HI converter intended for use with fully-synthesized 2-meter hand-held transceivers. Multiband operation will expand receiver coverage to 2400 possible channels. A replica of either the 154-158-MHz Public Service or the 159-163-MHz Marine Band is created at the receiver input. This allows reception of fire, police, sheriff, and other emergency services or coastal/inland marine communication, coast guard, and National Oceanic and Atmospheric weather service, respectively.

Frequency selection is achieved as normal through the keyboard or thumbwheel switches of the transceiver. Connection is made by simple series insertion between radio and antenna using standard BNCs. Operation with transceivers using threaded antenna mounts is achievable with readily-available adapters.

The passband of the HC-V includes the 2-meter band, enabling multiband as well as multi-channel monitoring with transceivers that have scanning capabilities. The combined sensitivity is much less than 1 μV for most transceiver/converter combinations.

An internal clamp network provides protection from accidental transmitter rf to both converter and transmitter for up to 5 Watts for up to 5 seconds. The "off" position disables all converter circuitry and restores normal transceiver operation without having to disconnect the HC-V.

The HC-V operates on a single AAA battery with an estimated battery life of up to 6 months or more at a use duty-cycle of 30-40%. The case size is 2-1/4" x 1-1/2" x 1-3/8".

For more information contact *M-Squared Engineering, 1446 Lansing Ave., San Jose CA 95118; phone (408)-266-9214.* Reader Service number 482.

LETTERS

HOLLOW WIN

Today, I received word from Bill Gosney, your Contest Editor, that I had been disqualified from *73 Magazine's* 1981 160-Meter Phone Contest due to excessive power output from my station.

First, let me say that I was not surprised and, second, that I plead guilty! But how, you might ask, did the contest committee come up with this information? Here is how.

After recopying my log sheets, duping, and finalizing my contest results (910 QSOs/ 400,000 points), I came to a paragraph on the summary sheet that required my signature. I had to swear that I had abided by all rules and regulations of *73 Magazine* and the FCC. Well, I could not bring myself to sign it because during the contest I used the home-brew linear (4-1000) that I had completed the day before the contest.

I know that if I had made my own summary sheet instead of using *73*'s, I could have avoided that hurdle like most of the other guys did, but I could not. Instead, I contacted Dan Murphy WA2GZB, the contest chairman, and informed him of the situation. He advised me to go ahead and send my logs into him, anyway.

I also told him that, in my opinion, everyone who had done really well in the contest also had used an rf amplifier of a power equal to mine. Dan acknowledged that he was aware of that fact and said those guys were not as honest as I in admitting to using an amplifier. I call these people hypocrites because they tell people they are using legal power and that their antennas are doing a spectacular job.

During the contest, my signals were never louder than those of some of the other big boys. Don't you find that interesting? I don't know of one contest station I have visited that did not have a 160-meter amplifier. Why all the secrecy? One has to use an amplifier on 160 during a contest to be competitive because everyone (or almost everyone) does. I would like to add that I did not use an rf amplifier before the LORAN shutdown in early January. I wonder how many other contesters can say the same thing.

I knew that I would be disqualified when I made these admissions, but I feel that about 90% of the other guys in the contest also should be disqualified or should at least have the guts to disqualify themselves.

Willy Worth WB3GCG
Brandywine MD

I admire your honesty, Willy. It's too bad you didn't let your conscience be your guide before the contest as well as after.

As a contester, I cannot understand what fun it is to win by violating the rules. To my mind, an operator who plays the game that way is no better than a small-town bully; he always gets his way, but so what?

A hollow victory is no victory at all.—Jeff DeTray WB8BTH.

NOISE-BRIDGE CORE

I am writing to point out a small error in your otherwise excellent article on the noise bridge ("QRM-Free Antenna Tuning, August, 1981).

The Indiana General core specified is made in a number of different ferrite "mixes" and you must specify which one you want. The commonly used one is the Q1 mix.

Also, Indiana General has changed their numbering system, so the CF-102 is now known as the F625-9. Thus, one should ask for F625-9 in Q1 mix.

If you order from Amidon, you should specify an FT-37 core with 61 mix if you want a core just like the F625-9 in Q1 mix. Are you confused by now? The T50-2 is an iron-powder core and, in my opinion, would not be as good as ferrite in this application.

Another way to get the proper core for this transformer would be to order from Palomar Engineers and ask for their F-37-Q1 core. This is exactly the same as the Indiana General F625-9 in Q1 mix. Send 60¢ each along with $1.50 per order shipping to Palomar Engineers, 1520-G Industrial Avenue, Escondido CA 92025.

Jack Althouse K6NY
Palomar Engineers

NOTES ON FLYING

In reference to "A Flier's Guide to the Airways," August, *73*, I have been an admirer of Jim Weir and the RST Company ever since its founding—a truly outstanding and innovative operation.

I do have a couple of nit-picks, however. First, one does not become aeronautical mobile until one is outside the limits of the continental USA. Otherwise, you are air mobile or simply mobile. By the same token, one does not become maritime mobile by being in a rowboat with an HT in a local lake.

Second, the article must have been in the editor's in-basket for a number of years [Are our faces red?—Editors]. Aviation gasoline now costs about $2 per gallon and the aircraft mentioned in the article would use at least $15 worth of fuel per hour.

The article was very useful to me because I had never heard of the Advisory Circular 20-98.

One problem Jim did not mention involving air mobile operation is noise. Most cockpits present a very noisy environment and the average microphone just can't cope with it. Even many of the "noise canceling" mikes don't hack the program. I use a Turner "Road King 50 Trucker's CB Special" and it is so effective that most people do not realize that I am in an aircraft (a noisy Mooney). Unfortunately, this microphone has been out of production for some years. If you see a used one, grab it.

Ken Hargrove W4OQP
Orlando FL

Thanks for the clarifications, Ken. Seems inflation has caught up with the magazine business in more ways than one.—Editors.

A PHOTON TORPEDO

I take exception to the theory put forth by W4FD and W4ATE (July, 1981, p. 52) that photons of light constitute the medium through which radio waves propagate. The theory sounds somewhat plausible, but has one major deficiency. Namely, if radio "waves" need some sort of medium to travel in (such as an "ocean" of light photons), then what sort of medium exists for the propagation of light "waves"?

Perhaps, the authors would suggest that since radio waves travel through light waves, then light waves must travel through X-rays and X-rays through gamma rays. In other words, perhaps there is an infinite succession of media, each having a shorter wavelength than its predecessor. But this is impossible, because the energy of photons increases as their wavelength decreases. An infinite series of media would require an impossible amount of energy.

The authors apparently would like to ignore the fact that light photons often behave like waves. Light has definite wave-like properties which easily can be demonstrated with a lens or diffraction grating. Now since a "wave" is usually interpreted as the propagation of some sort of "disturbance" through some sort of "substance," it is "logical" to assume that space is filled with some sort of "aether" which transmits "light vibrations." Of course, no such substance has ever been discovered (except for the ocean of photons proposed by the above authors).

Perhaps, the authors then might suggest that light waves are propagated merely by virtue of their particle-like properties alone. If photons are really particles, then they can travel through a vacuum without any assistance from a "medium" at all. We simply will ignore their wave-like features. But if this is true, then we don't need the authors' theory at all, because it turns out that radio waves also consist of photons and therefore would not require a "light-assist"! Radio and light are the same form of energy. The fact that radio photons have longer wavelengths has no bearing on the matter.

I also take exception to the authors' implication that a photon has a rest mass "as does any solid." The man who discovered the photon (Albert Einstein) proved that a photon cannot have a rest mass be-

cause otherwise it could not travel at the speed of light. A photon does have energy and this energy can be equated to mass by the famous $E = mc^2$ equation. Therefore, the more energetic a photon is (I.e., shorter wavelength), the more mass it will appear to have.

This apparent mass can be observed In such phenomena as the solar wind, as the authors correctly pointed out. But photons do not exhibit mass properties such as elasticity or rigidity, which are necessary for the transmission of vibrational energy through a physical medium.

Ormond Beach FL

That's easy for you to say!—Editors.

KUDOS

I was quite pleased to see a review of *The Radio Amateur's Conversation Guide* by the two very competent Finnish linguists OH2BAD and OH1BR in your July, 1981, issue. I previously had read of this book and its authors in the NRRL magazine, *Amatorradio*. In defense of the lack of a pronunciation guide in the book, I would like to make the following comments.

Given the international scope of this book, it would be almost impossible to give pronunciation guides in agreement with everyone's language. I will agree that there is a need for such a pronunciation guide, a need which could have been answered by use of the International Phonetic Alphabet (IPA). However, not everyone is familiar with the IPA, and extra pages would have been spent to explain the numerous phonetic symbols in each of the languages represented in the book. The availability of the cassette, therefore, is a much easier and more readily accessible answer to the need for a pronunciation guide.

Realizing fully that most Americans are considered almost as linguistically ethnocentric as French Quebecoises, the appearance and hoped-for acceptance of such a work as *The Radio Amateur's Conversation Guide* is heartening, to say the least.

The age-old myth of the difficulty in learning a second language is easily dispelled by the simple truth. Each of us had learned the essentials of one of the world's most notoriously confusing languages before any of us had learned to read or write. Adding another language is a simple matter of concentration, the same concentration that we all use to learn the International Morse code.

In passing, I might also add that Jukka and Miika Heikinheimo are both accomplished linguists. Miika is a scholar of ancient languages and theology, and Jukka, who studied Russian and Spanish at Helsinki University, operates a translation bureau, complete with computerized text processing equipment. Both are to be congratulated for this excellent book.

Si Habio dit-dit?—Editor.

MULTIMETERS

After reading your "*73 Magazine* Staff" article titled "Maximize That Multimeter" in the June issue, I feel compelled to write and give my feelings about some bad ideas expressed in this article.

First of all, a plastic meter case could render the unit worthless in the presence of typically encountered rf levels.

"Multimeters" generally do not have the need for three leads, but virtually all VTVMs do. The constant input resistance of VTVMs allows for the convenience of the important isolation resistor. A VOM, because of its input resistance change with range change, doesn't have this facility. For this reason, a VTVM is necessary for dc voltage measurements with the presence of a signal. The VOM without the isolation resistor tends to drastically affect the circuit impedance (especially video and rf circuits, but high-impedance hi-fi amp circuits are not immune). Rf getting into the VOM tends to be rectified by the commonly-used meter-protection diodes, causing erroneous readings. In our studio, a Simpson 260 VOM lying on the service bench will give a half-scale reading when the leads are inserted but not connected to a circuit.

At the transmitter, we have found that a VTVM with a 100-megohm resistor in place of the 1-megohm original has both given the scale a $\times 10$ factor and made it entirely immune to the presence of rf around the 5-megawatt ERP transmitter.

Using a meter which has a 1.5-V cell to power the ohmmeter section *may* produce enough voltage at the probes to turn on a silicon device, but does not do so for all conditions. For example, the full 1.5 V occurs at the probes only for infinite resistance, but at zero Ohms the voltage is zero. The amount of voltage at the probes is between zero and the 1.5 V as measured on a linear scale having 0 V at 0 Ohms and 1.5 V at infinite Ohms. A VTVM is the best meter to first visualize this relationship on. Therefore, simply use an ohmmeter range which gives a reading with less than about 0.25 V across the probes, and silicon devices are not turned on. The accuracy of this method is good enough for 99% of your service needs.

TORTURE

Concurrent with the ongoing debate about dropping the code requirement for a ham license, the media recently recounted an interesting story about one of our Vietnam POWs who used code to communicate with the outside world in an unusual way. To verify that the story is true, I wrote to the Honorable Jermiah A. Denton, Jr., now a Senator from Alabama, and he did indeed blink out "torture" with his eyelids while making a forced TV interview. A copy of his reply is attached.

Dear Mr. Crom:

I sincerely appreciate your comments of June 24, and am glad to respond to your request for my views on the Morse code requirement in FCC licensing of ham radio operators.

The FCC, as you are probably aware, has 2,400 personnel with which to supervise every facet of communications in the USA, with only 450 of these in the field. Rigid rules and reliance on self-policing from other operators are both logical and necessary.

Requiring proficiency in Morse code is one way, a good way—an economical way—to maintain both quality and discipline in what could quickly become a nightmare in amateur radio operations. In my particular case, had I not known Morse code, I would have been denied the one viable option of communication open to me while a prisoner of war, so I am definitely in favor of it.

Jeremiah A. Denton, Jr.
United States Senator
Washington DC

It is hoped that this incident will help motivate others to put in the little extra effort that will help keep ham radio from becoming an extension of the CB mess.

Russell C. W. Crom AG9N
Mt. Prospect IL

BEING POSITIVE

After being a subscriber and reader for quite some time, I thought I would drop a note to you and tell you how much I enjoy both your editorial and also your magazine. I always read your editorial first, followed by Awards, Leaky Lines, and Looking West. Keep socking it to those Connecticut "good old boys," Wayne. At least you seem to remember from week to week where you have drawn your lines.

I don't know if you still plug dealers in your magazine but if so, please log up a couple of gold stars for the Electronic Center in Lincoln, Nebraska. I acquired a Kenwood TR-7800 from them at a recent hamfest in St. Paul. The nicads used for memory retention would not charge. I called them up on their toll-free number and they advised me to send it to them. I did so and had it back in 12 days fully operational. Their tech claimed pilot error for the malfunction, but whatever the reason, it works fine now.

Bob Cronberg KBØXR
Plymouth MN

Wayne, Bill, Dave, and Bill appreciate your pat on the back, Bob. Any fans of our other columns out there?—Editors.

MR. DX

I would like to express how much I enjoy the new DX column by Yuri VE3BMV. This is not the kind of DX column that I am accustomed to reading in any other monthly ham radio magazine.

His column has real information that can be used on the air, up-to-the-minute info on the rare ones, and great operating aids for the DX hunter. It is obvious that Yuri has a great deal of knowledge of DXing, and is not reluctant to share it with us.

I look forward to this valuable addition to *73 Magazine.* You fellows at the front office have really snagged a rare one by getting Yuri.

Ron Brown WA3CEC
Dundalk MD

Sh-h-h-h! We don't want Yuri to get a big head.—Editors.

BOHME?

In your editorial in the July issue of the magazine, you mentioned possible implemenation of types of high-speed communication. I have had some experience in Bohme, which at the time had capability of 600 wpm. This was in 1943 when I was CO of WVNT, the hub of Signal Corps communication in the Middle East.

It is my belief that this was the first time the Signal Corps attempted to operate their own 40-kW point-to-point station outside of the USA. The location was Asmara Eriteria, elevation 7600' above the Red Sea port of Massowa, and 65 miles by road from there. The station was fitted with punched tape (Kleinschmidt, or Bohme) transmitter heads, and the receivers were located 6 miles away with triple diversity operation output back to transmitter location where the tapes were made for retransmission via Manual Station to Cairo, the Persian Gulf, and other stations. We also handled all communication for the operations in north Africa until the invasion of Oran and Algiers, when a similar station was set up there (Algiers).

Today, with solid-state equipment (Hal) I find that 200 wpm is possible, and understand that printers are available commonly to 600 wpm. My Hal equipment will print (on monitor) 300 baud, 30 characters/second, or 1800 characters/minute, or 360 words/minute. This is not bad for starters. I have experimented personally with 100 to 150 words/minute. I am going to try to work out something with a friend who has the same equipment I have, and will report results.

I would appreciate any feedback that can come about as a result of this work, I have a kW to a 20-meter dipole and about 600 W possible on 15 and 40 meters where, unfortunately, few RTTY stations operate. I have not tried 75 meters, where I have heard some operators.

Henry B. Plant W6DKZ
4160 Holly Drive
San Jose CA 95127

CW at 200 wpm? It's a good start, but we can do even better. Let's get some reliable 1200-baud ASCII systems working. The FCC seems receptive to STAs right now. Don't forget to write it up for 73.—Editors.

KAHANER REPORT

Larry Kahaner WB2NEL
PO Box 39103
Washington DC 20016

FOR WHOM THE BELL TOLLS

AT&T and the Bell operating companies no longer have the only wheel in town. You've seen the commercials for a company called MCI: "You haven't been talking too much, just paying too much!" MCI, a company which didn't exist until several years ago, offers a cut-rate long-distance service which pushes AT&T long lines out of the picture.

The system is ingenious but at the same time simple. You dial a local access number (5 digits); when you hear the beep, you enter a 6-digit code number (that's so they know who to bill the call to), then the area code and phone number you want.

The call is routed from the local access number through a network of microwave relays until it reaches the final destination area. Then the call connects back into the local phone network and your hookup is completed.

As I said, simple. Ma Bell is cut out of the action except for the two local calls.

AT&T tried to keep MCI from skimming the cream off the long-distance business, wouldn't connect their network, and generally made life miserable for the company. MCI took them to court and won a whopping $1.9 billion. AT&T is, of course, appealing the decision.

Don't get me wrong. AT&T did have reasonable grievances about the new kid on the telephone block. AT&T invested in an entire network, local and long distance, and MCI is taking the most lucrative part away. It's difficult sometimes to feel sorry for a monopoly which racked up a $6-billion profit last year, but they do have a point.

Anyway, MCI is doing very well. 1981 fiscal year net income totalled $21 million.

Ironically, they're still not happy. They don't want their customers pressing so many buttons. They want you to hook directly into the local phone loop without all the fingerwork.

AT&T maintains it isn't possible. MCI says it is, and they proved it. MCI cut a deal with a small independent telephone company in northwest Iowa—Northwest Iowa Telephone. NIT's 2,100 customers in three Iowa cities have an equal choice between dialing via AT&T or MCI.

If a caller dials "6," then the 10-digit long-distance phone number, he goes MCI. It he dials "1," then the 10-digit long-distance phone number, he travels AT&T. Service was expected to begin Aug. 1.

MCI President Bill McGowan told a group of reporters, "AT&T could do this for us, but they don't want to. AT&T argued that it couldn't be done, but this agreement proves otherwise."

One funny note in all of this: The agreement was broached by the small telephone company to protect its interests from MCI which was planning facilities in Sioux City, an area partially serviced by NIT. MCI would have siphoned off some of the long-distance revenue which AT&T kicks back to the local operating companies. MCI, which used to fight the big bully, was, in this case, a bully itself.

And a footnote—Why did MCI choose the number "6"? Well, because it corresponds to the letter "M" for MCI!

Okay. So MCI—and to some extent Southern Pacific which operates the SPRINT system—have installed networks to replace long-distance service. Bell still has the local loops, right? Yes, but even that's up for grabs. It began about five years ago when Xerox proposed something with the space-aged name of XTEN. It was to be a local digital network, mainly for high-speed data traffic to and from major metropolitan areas.

This was the plan: Xerox was going to install a centrally-located microwave dish on the tallest building it could find. (The second tallest would have worked, too.) Then on your office building, you install a microwave dish which feeds data from you (by way of a network inside the building) to the central dish. The data is then sent via satellite or AT&T long lines. You bypass the local phone company, which can't carry high-speed data in most cases, anyway. Of course, you're not the only one using the system; others in your area are doing the same thing, using dishes on their buildings. Xerox envisioned a mini-network feeding into one, possibly two, central points.

Xerox convinced the FCC that this was such a good idea that the Commission authorized DTS, Digital Termination Service, in the 10-GHz range. Xerox couldn't be happier. After all, they were the only ones thinking of such a thing, and they expected to clean up.

Well, things got a little out of hand. Management appeared unstable; changes were made. In short, way behind schedule and a couple of bucks behind, Xerox dumped XTEN earlier this year.

But alas! Another company (named ISACOMM) has jumped into the scene and asked the FCC for permission to offer a similar service.

Local users, once they connect via microwaves to the central point, will have their messages transmitted by satellite to

users in other cities with the same setup. Not only is AT&T out of the long-distance action, but out of the local action as well.

ISACOMM is owned by Insurance Systems of America, a consortium of insurance companies. The reason why they backed the network seems clear. Insurance companies must move lots of high-speed data quickly and cheaply.

But ISACOMM isn't stopping there. According to the filing, the firm plans videoteleconferencing, voice, and other services. Although the intent, at first, is clearly to serve its backers, it may, one day, expand to the consumer.

The initial plans call for the linking of 30 cities. The first central site is Atlanta.

So, what have we got here? Competition for AT&T and the local Bell operating companies for the very first time.

Don't ask for whom the bell tolls, Ma Bell. It tolls for thee.

JUST FOR THE RECORD

The FCC has added some new commissioners: Henry Rivera, a New Mexico lawyer, and Mimi Dawson, a congressional aide. This complements the full commission, consisting of Chairman Mark Fowler, James Quello, Joseph Fogarty, Abbott Washburn, and Anne Jones.

In a personnel change more directly affecting hams, we learned at deadline that Carlos Roberts, chief of the private radio bureau, was planning to leave at the end of August. He was offered a job as director of land mobile development for M/A Com Labs in Gaithersburg, Maryland. You may know M/A Com as the parent of Microwave Associates, a firm that sells microwave gear for amateur use.

His replacement will be James McKinney, now chief of the field operations bureau. McKinney is well respected and has always held ham radio in high regard. On several occasions, at FCC meetings, McKinney has called amateurs the best disciplined group that the Commission manages. Maybe he hasn't listened to 80m lately, or perhaps his 2m rig is on the blink. Or maybe, just maybe, compared to everyone else, we're tame. That's a scary thought.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 8

right outside the back door of the room. Chuck and Tim quickly put up an antenna and were batting 'em out on 15 meters. I was able to get in edgewise and operate, but most of the time the band was open to Europe instead of the US. I didn't find the pileups that I did when operating from Turks and Caicos Islands.

The next morning we had an appointment with the Prime Minister of the country. He wanted to thank me for sending Tim down last year with the four trunks of ham gear to help them after the hurricane. That was the worst hurricane the island had had in a hundred years or so. It wiped out most of the banana crop, demolished hundreds of buildings, and screwed things up for a long time to come.

This gave me an entry to talk about the possible development of ham clubs on St. Lucia to get teenagers interested in amateur radio. The PM was very interested in this and I think we may be able to get that started. The idea is simple... interested hams or clubs in the US could provide the funds for club stations to be set up in youth centers in St. Lucia. Their government would provide someone to teach the fundamentals of electronics and radio, while the students learned about operating by running the club stations. Thus, the youngsters would get the enjoyment and enthusiasm of being able to operate while they are learning the basics of radio. With this grounding, the teenagers would have a head start toward technical careers in electronics or communications. Technical people are needed desperately in small countries such as St. Lucia.

This plan is similar to the one I outlined for Jordan and which got their youngsters started in careers in electronics.

If any hams or clubs are interested in helping this project, I think we can furnish a first-rate club station for about $1,500, buying the equipment at wholesale. Part of the bargain is an opportunity to make a visit in a year or two and see the hams which your station has developed. I would like to have as many hams as possible share the thrill I had when I visited Jordan and had a chance to meet the hundreds of young hams which my first visit had brought about.

St. Lucia has an advantage over most countries in that there is no duty on ham equipment. Canada managed to cost itself millions of dollars in lost technicians and engineers by putting a heavy duty on ham gear. Indeed, there are many countries where just the duty alone on a small rig is more than the average educated local earns in several months. I'm not talking about a sideband rig—just a simple CW transmitter. I remember talking with a ham in Egypt who had to spend four months' wages to import a ham rig sent to him by an enthusiastic American ham. It *could* have been done at less expense if the American ham

That's the Prime Minister talking with me... with Tim to the right of me and Chuck to the left side of the picture.

The small and crowded streets of Castries on St. Lucia are jammed with traffic much of the day... just like New York. The pace of life there is slower and the prices more reasonable. Note the lady with the bundle on her head. Most of the cars were Japanese... with some Russian versions of the Land Rover growing in sales.

had sent it in pieces, but even so, the duty would have been painful.

St. Lucia is a wonderful place to visit, but I discovered that a visit can be dangerous. I found several Americans living on the island. They came down just for a visit, found out about the low cost of living there and the beauty of the island...and moved down. I understand that one can rent a small house on St. Lucia for about $100 a month. And, while most of the bananas are exported to Britain, you can live economically on local foods.

By the way, bananas grow quickly, so the devastation of 1980 was already just a memory. Each time a banana plant grows and provides its bananas, it is cut down and a new plant grows from the roots. Fresh pineapples, coconuts, mangoes, papaya, sugar apples, and so forth are growing all over the island.

The hams on St. Lucia reflect a wide area of interests. One runs the electronics store in Castries, the main town. Another is a lawyer. Another runs the yacht club (and issues the ham licenses).

We were taken on a trip around the island, all the while in touch with most of the active hams via the .34/.94 repeater. This was a beautiful trip, showing us the dry, the rainy, the mountains, and the flatlands which make up this small island. It's about 40 miles from one end to the other. I hope you'll get a chance to see my slides.

On the southern tip of the island, we went to the top of a mountain and I had the kick of working a chap who was visiting Barbados. Not bad for a 2m hand transceiver.

We enjoyed meeting the businessmen of St. Lucia at the Rotary meeting, and the hams got together for a big cocktail party, complete with marvelous snacks...and Miss St. Lucia, the recent winner of the island beauty contest.

None of the hams was into scuba diving, but they did take us to St. Lucia Divers, where Chuck, Tim, and I arranged for a dive trip. Actually, Chuck and Tim went snorkling while the divemaster and I went down with scuba gear. I had along my camera and a new flash unit, and snapped pictures until the film was done. The dive spot was beautiful, even if it was about 20 miles down the coast from Castries...a long, bone-jarring boat ride. The underwater scenery was great for both snorkling and scuba, with a headwall going down sharply for the adventurous. There were plenty of gorgeous coral formations and colorful fish.

After the dive, we packed up and went a boat-banging twenty miles back to Castries. I think the ride was more exhausting than the dive. Anyone with a tendency toward seasickness should not make that trip. Sherry wisely opted to hear all about it later. She'd made a similar trip with Chuck and me at Turks and decided not to go through that again. The next trip to St. Lucia, I think we'll stay at the hotel right by the diving spot...near the town of Soufriere.

The four-day extended weekend "vacation" was over all too soon. Our hosts picked us up at around 6:00 am and drove us the hour and a quarter to the airport and we were on our way. The plane stopped for a few minutes at Guadeloupe, but they wouldn't let me off to collect one more country visited.

We soon were back in the air with the next stop St. Croix, where they have an international airport. Here, we had to get off the plane and go through US Customs. I declared the only thing I'd bought...a straw hat. On the next hop, we flew over Puerto Rico, where I was able to take a long shot of the disk at Arecibo, and then on up the islands. We went right over Providenciales, where we had visited in March, and I took a picture of the Bob Cooper estate and TV receiving dish. Soon we were in Miami and then on our way to Washington...and Boston.

Speaking of Miami, on our way down to St. Lucia we had to stop there. We were met by two good friends of Tim's, Don and Mary Johnson, who took us for a visit to N&G Electronics...and a Mexican lunch. They made the stopover between flights a fun time. I was particularly impressed by the N&G store and the amount of ham gear they have in stock. They showed me the plans for their new store, which they will be starting on soon. It will be in the same general area, not far from the airport, but will be much larger. A good deal of their business comes from Latin America.

Outside of a short DXpedition to Swaziland and Lesotho in August, I had nothing much planned for a while. Those countries were to take me over the 100 mark in countries visited. Should I start working for 200 or just settle down and take it easy? I was on the air from both of them, as well as South Africa.

INFORMATION STATIONS

At long last, microcomputer technology is beginning to really get involved with amateur radio. There is no question in my mind but that it is going to take over and amateur radio will never be the same.

You've probably at least seen pictures of the Radio Shack pocket computer. Well, this is not a very big computer, but it is a decided development over the pocket calculators. It has a small BASIC language built in, so it can be programmed to do almost anything...and that includes some word processing.

A recent development in this line is the new Casio pocket computer (FX-702P)...a six-ounce computer with a five-pound manual. This, along with the Sinclair ZX-80, which is selling for $150 to $200 most places, could be mated with a ham rig to provide a sort of instant message service. Let me go into that in more detail.

Those of you who are already busy with microcomputers are aware of the growing interest in telephone bulletin boards, data services, and that sort of thing. Well, these can just as well be organized over the air. Instead of having a W1AW sending hours and hours of voice and CW messages every day, a radio bulletin board (RBB) station could sit, listening to a channel, for any inquiries. A request would bring on the sending in ASCII of a message which would be a menu of what is available from the RBB station.

The inquiring station would then select some part of the menu and ask for that information...which would be sent by the RBB station. What sort of information would be appropriate? Well, how about the latest in DX news, listing calls, QSL managers, times and frequencies, dates of expected operation? New countries then could be found easily. Or, how about Westlink news? Or other news reports? Then we could have the latest in FCC news, with release, proposed rule changes, dockets, and the dates for comment, perhaps even some ideas on the dockets to help amateurs explore all aspects of the proposed rule changes.

There are many information broadcasts which would be of value to amateurs, once we get to thinking about them. We could have a repeater update, hamfest information, a net directory listing all active low-band nets, their frequencies, times, and special interest. Traffic nets could be listed. Satellite information. The more you think about it, the more information comes to mind which would be of interest.

Using the old 300-baud standard, which to me is about like forcing everyone to send Morse code at two words per minute, we could send about 230 words per minute. This, as I mentioned recently, is the reading speed of a very slow reader. This makes as much sense as two words-per-minute CW. I think we'll have to start out with that, but I would suggest an immediate push for 1,200 baud as quickly as possible. That brings us up to about 1,000 words per minute, which is a lot better...but nowhere near what we really want.

Since 9,600 baud is being used with success over ordinary telephone lines, I would recommend that we move in on that standard. That would give us around a 7,300 words-per-minute transfer of information. Now we're talking a second or two for each transmission and the ability of many stations to access the RBB station in a short time.

HOW IT MIGHT WORK

Let's imagine our bulletin-board station set up on a synthesized channel. Let's further ask it to identify occasionally and send out regular pulses to hold the channel...perhaps one every second.

If I want to check on the latest DX news, I would type in "M?" on my built-in microcomputer system. Then, the next time the RBB polled the channel my rig would respond with that request for the menu. The RBB would immediately send a "bullipp" which would read out on my screen as the menu of information available. Number 7 might be my hot DX news, so I would type a "7" and a half-second

later, the RBB would poll my rig and trigger it to send the "7". The RBB would then dump the DX news, which might sound like a "beedlerupp" and I could then read out the hot scoop from my screen.

Obviously, we're going to have to experiment with error-correcting codes which will tell the other station how many bits of information are going to be exchanged. If the right number does not get through, the message can be repeated...or the missing part of it repeated. We're talking milliseconds, but we still may have to cope with CW jamming and other aggravations.

TRAFFIC HANDLING

Once we have a communications system which will perk along dependably at 7300 words per minute, we obviously have made it possible for a way to handle traffic that will knock the sox off voice or CW message handling. Not only can our messages go through without error in a second or two, but we also can address them for automatic relaying on any band. Relaying stations can be set up to poll a channel for traffic going to that area, perhaps pulsing every minute or so with a quick identifier. A hundred relay stations could all use the same channel without interference.

And once we are set up for that, imagine the value of this system for emergencies. A small pocket computer plugged into our mobile rig would enable us to join such an emergency net and have our traffic sent and received...or relayed...all automatically. Voice may be a little easier to use, but the speedy, error-proof digital system would win out. Of course, they are working hard on voice-to-digital encoding systems. They may eventually get one which works well. Going from digital to voice is a lot simpler...that's even built into my pocket Talking Clock now. And I saw talking wristwatches at the Consumer show in Chicago. They were junky, but a hint of what is coming.

EXPERIMENTING

I assume that we will have the usual number of hams who will do everything in their power to try to fight progress, complete with jamming experimental message-handling stations. Well, you may be able to drive a few pioneers up the wall, but you really are not going to be able to stop the marriage of computers and amateur radio. If you can't help us to grow and invent new communications techniques, at least don't make it so difficult for those of us who are really trying.

I came into amateur radio not very long after the last spark transmitter had been outlawed. If you read your old magazines, you'll find that there were a bunch of old-timers hanging in there, chanting "spark forever" right up to the minute it was illegal for them to use those rigs. They fought progress as hard as they could. We had a similar situation with sideband, with old-timer AMers hanging *in* there, bitching and moaning and making a mess out of the bands.

Will CW finally blow away as the cost of microcomputers keeps coming down and a computerized communications system is not much more expensive than a CW rig with a keyer? Well, who needs five words per minute when the same rig can shoot out 7300? For what? For emergencies? Hell's bells, if there ever is a time when we need automated fast communications, it is during an emergency. We need to be able to hook mobile, hand-held rigs, low bands, satellites, repeaters...everything together automatically. If we have the system going on an everyday basis, we'll have it there when we need it.

With satellites tied in, we will be able to reach any amateur in the world via autocall through our traffic-handling nets. We'll have instant access to enormous amounts of information through RBB stations. And the best part of it is that we really have very little to invent. We already have most of the basics that we need, with experimentation required to find out the best way to get it all to work...and then time to get enough amateurs involved to make the system work.

WHAT'S WAYNE DOING?

This is more of a letter to the several thousand personal friends who read *73* every month. Hello, Shep....

80 Microcomputing, which I started last year, is doing exceptionally well, running about 300 pages and more per month. I've also started a monthly dump of the programs from this magazine on cassettes called Load 80...another winner. Then there is the *Encyclopedia 80,* a monthly book of material on the TRS-80...things not published anywhere else...and a cassette dump of the programs for this called Encyclopedia Loader. That brings the monthly publications to eight, if we include *Desktop Computing.*

There are six more publications in prospect, including one for satellite TV, one for women's health, an Apple magazine... and so on. *Deskop Computing* will be out this month, the first computer magazine written totally in plain language.

As if that isn't enough to keep track of, we are working toward starting a technical institute to teach microcomputers, electronics, and publishing. I'm hoping that something can be done to get our government to help students from Third World countries to come and get an associate degree in electronics so that they will be able to go back home and help the growth of communications...and education.

Russia and Cuba are still going strong helping emerging nations with education, but their education has that political flavor we really don't need today. I wish that the US would recognize the importance of helping smaller countries develop and not ignore them until it is too late.

The Instant Software division is in a fast-growth mode. It takes up most of the Elm Street building and has the largest microcomputer lab in the world. Over 10,000 programs have been sorted through and evaluated, with about 1,000 being okayed for mass publication. Most of these are for the TRS-80, but we're making a major effort to get these converted for use on the Apple and Atari. We're also working to get programs written or converted for the Casio computers...the 702P and their new 9000.

My recent visits to the major microcomputer firms have been encouraging. A year ago, none of them really appreciated the importance of software to the sale of their product...now only Radio Shack seems to still have its corporate head in the software sand. This could be the breakthrough that Apple needs to get ahead of Tandy. Of course, this means more and more business for Instant Software.

Our Irish plant is now running, supplying software for Europe and Africa. I was in Africa for three weeks in August. There was a microcomputer exposition in Johannesburg, and I spoke there on world microcomputer industry trends, software developments, and so on. I also had an opportunity to address the Apple dealers and bring them up to date on the world Apple situation.

Outside of that...and being the president of the Peterborough Chamber of Commerce this year, I'm loafing around. As Dorothy Parker once wrote, burning your candle at both ends makes such a pretty flame.

HAM HELP

I'm looking for ham call license plates for my collection. I would like to swap for or buy plates from other states and provinces.

Does anyone know of any CW nets that a greenhorn might be able to check into to improve his CW operating proficiency? I'm not permitted to handle third-party traffic and even in the Novice band I get clobbered by QRM. Any suggestions would be appreciated. Many thanks.

OSCAR ORBITS

Courtesy of AMSAT

TUNING IN TO OSCAR 8

OSCAR 8 is the only amateur satellite available for everyday communications. Using the satellite for two-way contacts requires a 2-meter signal of about 100 W ERP. This can be achieved either by using a linear amplifier or by erecting a high-gain antenna which is movable in both azimuth and elevation. Such complexities are unnecessary, however, if you simply want to listen to OSCAR 8. In fact, listening to OSCAR 8's 10-meter downlink is a fairly simple procedure and an excellent introduction to the fun of satellite communications. The satellite operates in Mode A (10-meter downlink) on Monday, Tuesday, Thursday, and Friday. The only equipment required is a receiver capable of tuning the high end of the 10-meter band and an omnidirectional antenna or dipole for 10 meters. You will also need some idea of when the satellite is in range. The simple method outlined below will help you determine when to listen for OSCAR 8, and it requires nothing more than a pencil, paper, and a pocket calculator. The method works satisfactorily for all locations in the northern hemisphere.

WHEN AND WHERE

The first step in using the data in the chart of orbital information on this page is to divide a sheet of paper into three columns labeled "Orbit No.," "Time," and "Crossing." Select a day that OSCAR 8 is scheduled to be in Mode A, and write the corresponding orbit number from the chart in your first column. Then get the time and equatorial crossing longitude from the same row of the chart and write them in the second and third columns. You should now have one row of data on your paper, the same data found in the chart for the date you have selected. At this point, you are ready to calculate the equatorial crossing time and longitude for each orbit of the selected day. A pocket calculator will be helpful for this, but even so, the process will be time consuming. We all must make sacrifices in the name of progress!

Now, add 1 to the orbit number and write the result just below the first orbit number. Add 103 minutes (1 hour, 43 minutes) to the original time in row one and write the result in column two of the second row. Finally, add 26 degrees to the longitude in row one and write the result in column three of row two. You should now have two complete rows of data in the homemade table you are constructing. Repeat this procedure, adding 1, 103, and 26 to the most recent numbers in columns one, two, and three until the total in column two exceeds 2400 hours, indicating that you have reached the end of one day's calculations. Whenever the total in column three exceeds 360, simply subtract 360 from the number before writing it into the table. There should be 14 or 15 rows of data in your completed table.

What you have just done is to develop a table showing the orbit number, crossing time, and equatorial crossing longitude for each orbit in the selected day. In essence, you have filled in the gaps in the charts printed in the magazine, which show data for only the first orbit of the day. A new table must be created for each day you plan to listen for OSCAR 8.

We are almost ready to choose a time for listening to OSCAR 8, but you must first determine your longitude. This is easily done by consulting a road map, most of which show longitude and latitude around the perimeter. Now examine your homemade table. Scan the third column, looking for crossing longitudes which are between approximately 10 degrees west of your longitude and 35 degrees east of your longitude. You should find two or three suitable longitudes in your table. When you find them, go across to column two and circle the times corresponding to these longitudes. On the day in question, those are the best times to start listening for OSCAR 8. If you live near the equator, you will begin to hear the satellite a few minutes before the calculated time, while more northerly listeners will hear it after the calculated time.

This is a relatively crude calculation, but it should allow you to hear OSCAR 8 reliably. It is important to remember that the satellite operates on Universal Time (UTC). Thus, when we speak of Monday being a Mode A day, we are referring to Monday UTC, not Monday local time.

WHAT YOU'LL HEAR

The OSCAR 8 10-meter downlink spans the frequency range from 29.400 to 29.500 MHz. A Morse telemetry beacon on 29.400 MHz transmits continuously at 20 wpm, sending coded information about the condition of the satellite. The telemetry consists of several groups of three digits each. Listening for the telemetry beacon is a good way to be sure you are hearing OSCAR 8 and not some other amateur activity on the same frequency.

When the satellite is in range, you will hear many QSOs in progress simultaneously in the 100 kHz that comprises the communications passband. Although satellite users tend to stick to a band plan which calls for CW at one end of the passband and SSB at the other, there is considerable mixing of the modes. OSCAR contacts tend to be short, since the satellite is in range for a maximum of only 20 minutes.

If you have 435-MHz receiving capability, try listening to OSCAR 8's Mode J transponder. Its downlink is 435.100 to 435.200 MHz. Mode J is activated on Saturday, Sunday, Tuesday, and Friday (note that OSCAR 8 is in Modes A and J simultaneously on Tuesday and Friday). The Mode J telemetry beacon can be found at 435.090 MHz.

You may have noticed that Wednesday is not mentioned as either a Mode A or Mode J day. This is because Wednesday is set aside for special experiments and the satellite is not available for normal communications use, although you are welcome to listen to the day's activities.

When listening to OSCAR, you will notice that the frequency of the transmissions from the satellite is constantly changing. This is the famous Doppler shift, caused by the high relative velocity between you and the satellite (thousands of miles per hour!). You will need one hand on the tuning knob almost continuously during an OSCAR 8 pass.

OSCAR represents an exciting opportunity to learn and perfect a new communications technique, and listening will get you started. For more information about amateur satellites, write to the Amateur Satellite Corporation (AMSAT), PO Box 27, Washington DC 20044.—WB8BTH.

HAM HELP

I would like to contact anyone concerning the construction of the "Heterodyne Deviation Meter" as published in the ARRL *Radio Amateur's Handbook* and in the *FM and Repeaters Handbook*. In particular, I need to know the type of crystal used.

Dave Harper W4NIQ
Route 2, Lincove
Fayetteville TN 37334

I am looking for a schematic or manual on several pieces of equipment: (1) Sylvania Electric TV marker generator, type 501; (2) Weston model 779 Analyzer VOM; (3) Hallicrafters model S38C; (4) RCA Voltohmyst #195A. I will be glad to pay for any copying costs.

Lorin McNutt KA9BZP
5460 West 1200 South
Fairmount IN 46928

I need information on a crystal filter marked as follows: Filtech Corp. Crystal Filter C.F. 7.825 MHz—model 2131 P/N 780055. I believe this unit was made for Hy-Gain equipment and will greatly appreciate any data on: (a) no. of poles; (b) bandwidth @-6dB and @-60dB; (c) impedance in and out; (d) insertion loss in dB; (e) present address of Filtech Corp. Thank you.

C.A. Carhoun, WB1ACU
11A Harold Street
Harwich Port MA 02646

I am looking for a source of technical information on the VHF/UHF Radio Telephone Service, i.e., IMTS, MTS, etc. Any information will be appreciated

G.S. Wienand WD4DLY
312 Madison Ave.
Cape Canaveral FL 32920

I need a manual and schematic for the following: Hammarlund HQ-170 receiver, Heath MM-1 multimeter, United Electronics Laboratory (UEL) model F 5-inch oscilloscope (schematic only for the scope).

William N. Richmond WD4CPQ
122 E. Adair St.
Louisville KY 40214

I am in need of a schematic diagram for a Heathkit Twoer, model HW-30. I will be glad to pay any reasonable duplicating and mailing costs, or I will duplicate on receipt and send back by mail.

David Snell KA7INW
324 Galaxy Drive
Butte MT 59701

Subscription Problem?

73 Magazine does not keep subscription records on the premises, therefore calling us only adds time and doesn't solve the problem.

Please send a description of the problem and your most recent address label to:

Farmingdale, NY 11737

Thank you and enjoy your subscription.

DEALER DIRECTORY

Phoenix AZ

The Southwest's most progressive communications company stocking Kenwood, Icom, Yaesu, MFJ, B&W, Astron, Larsen, Cushcraft, Hy-Gain, Bearcat, and more. Would like to serve you! **Power Communications Corp., 1640 West Camelback Rd., Phoenix AZ 85015, 241-Watt.**

Culver City CA

Jun's Electronics, 3919 Sepulveda Blvd., Culver City CA 90230, 390-8003. Trades 463-1886 San Diego. Call us for a low quote.

Fontana CA

Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lunar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, landmobile. **Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.**

San Jose CA
SAN FRANCISCO BAY AREA

Homebrewers' haven; tons of new and used Ham/Computer gear and components. Serving Hams since 1958. We specialize in ICOM, KLM, Mirage, Comptronix. We ship worldwide. **Tele-Com Electronics, 15460 Union Avenue, San Jose CA 95124, 377-4479.**

San Jose CA

Bay area's newest Amateur Radio store. New & used Amateur Radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santec & many more. **Shaver Radio, Inc., 1378 So. Bascom Ave., San Jose CA 95128, 998-1103.**

Denver CO

Experimenter's paradise! Electronic and mechanical components for computer people, audio people, hams, robot builders, experimenters. Open six days a week. **Gateway Electronics Corp., 2839 W. 44th Ave., Denver CO 80211, 458-5444.**

Miami FL

Amateur Radio Center, Inc. "Everything for the Amateur" Since 1960. **2805 N.E. 2nd Avenue, Miami, Florida 33137, 573-8338, TWX 522035.**

Columbus GA

KENWOOD—YAESU—DRAKE

The world's most fantastic amateur showroom! You gotta see it to believe it! **Radio Wholesale, 2012 Auburn Avenue, Columbus GA 31906, 561-7000.**

Smyrna GA

For your Kenwood, Yaesu, ICOM, Drake and other amateur needs, come to see us. **Britt's Two-Way Radio, 2506 N. Atlanta Rd., Smyrna GA 30080, 432-8006.**

Preston ID

Ross WB7BYZ, has the Largest Stock of Amateur Gear in the Intermountain West and the Best Prices. Call me for all your ham needs. **Ross Distributing, 78 So. State, Preston ID 83263, 852-0830.**

Terre Haute IN

Your ham headquarters located in the heart of the midwest. **Hoosier Electronics, Inc., #9 Meadows Center, P.O. Box 3300, Terre Haute IN 478003, 238-1456.**

Littleton MA

The ham store of N.E. you can rely on. Kenwood, ICOM, Wilson, Yaesu, DenTron, KLM amps, B&W switches & wattmeters, Whistler radar detectors, Bearcat, Regency, antennas by Larsen, Wilson, Hustler, GAM. **TEL-COM Inc. Communications & Electronics, 675 Great Rd., Rt. 119, Littleton MA 01460, 486-3040.**

Medford MA

New England's Distributor and Authorized Service Center for all Major Amateur Lines. Located Just North of Boston at Exit 5 on I-93. **Tufts Radio Electronics, Inc., 206 Mystic Ave., Medford MA 02155, 391-3200.**

Ann Arbor MI

See us for products like Ten-Tec, R. L. Drake, Dentron and many more. Open Monday *through Saturday, 0830 to 1730.* WB8VGR, WB8UXO, WD8OKN and W8RP behind the counter. **Purchase Radio Supply, 327 E. Hoover Ave., Ann Arbor, Michigan 48104, 668-8696.**

St. Louis MO

Experimenter's paradise! Electronic and mechanical components for computer people, audio people, hams, robot builders, experimenters. Open six days a week. **Gateway Electronics Corp., 8123-25 Page Blvd., St. Louis MO 63130, 427-6116.**

Phila. PA/Camden NJ

Waveguide & coaxial microwave components & equipment. Laboratory grade test instruments, power supplies. Buy, sell & trade all popular makes, HP, GR, FXR, ESI, Sorensen, Singer, etc. **Lectronic Research Labs., 1423 Ferry Ave., Camden NJ 08104, 541-4200.**

Somerset NJ

New Jersey's only factory authorized ICOM and YAESU distributor. Large inventory of new *and used specials. Most major brands in stock.* Complete service and facilities. **Radios Unlimited, 1760 Easton Avenue, P.O. Box 347, Somerset NJ 08873, 469-4599.**

Amsterdam NY
UPSTATE NEW YORK

Kenwood, ICOM, Drake, plus many other lines. Amateur Dealer for over 35 years. **Adirondack Radio Supply, Inc., 185 West Main Street, Amsterdam NY 12010, 842-8350.**

Central NY

Amateur radio hardwood displays made to your specifications: callsigns, plaques, awards or special orders. High quality, fast service, low prices. **A.&M. Woodcraft, 313 N. Madison St., P.O. Box 243, Rome NY 13440, 337-5642.**

Syracuse–Rome–Utica NY

Featuring: Kenwood, Yaesu, ICOM, Drake, Ten-Tec, Swan, DenTron, Alpha, Robot, MFJ, Tempo, Astron, KLM, Hy Gain, Mosley, Larsen, Cushcraft, Hustler, Mini Products. You won't be disappointed with equipment/service. **Radio World, Oneida County Airport-Terminal Building, Oriskany NY 13424, 337-0203.**

Columbus OH

The biggest and best Ham Store in the midwest featuring quality Kenwood products with working displays. We sell only the best. Authorized Kenwood Service. **Universal Amateur Radio Inc., 1280 Aida Dr., Reynoldsburg (Columbus) OH 43068, 866-4267.**

Scranton PA

ICOM, Bird, CushCraft, Beckman, Fluke, Larsen, Hustler, Antenna Specialists, Astron, Avanti, Belden, W2AU/W2VS, CDE, AEA, Vibroplex, Ham-Key, CES, Amphenol, Sony, Fanon/Courier, B&W, Ameco, Shure. **LaRue Electronics, 1112 Grandview St., Scranton PA 18509, 343-2124.**

Dallas TX

Used computer terminals, printers, modems, surplus, electronic parts. Hours: 12-6, T, W, T. **Rondure Company, "The Computer Room," 2522 Butler St., Dallas TX 75235, 630-4621.**

Houston TX

Experimenter's paradise! Electronic and mechanical components for computer people, audio people, hams, robot builders, experimenters. Open six days a week. **Gateway Electronics Inc., 8932 Clarkcrest, Houston TX 77063, 978-6575.**

San Antonio TX

Complete 2 way service shop. Call Dee, W5FSP. Selling Antenna Specialists, Avanti, Azden, Bird, Hy-gain, Standard, Vibroplex, Midland, Henry, CushCraft, Dielectric, Hustler, ICOM, MFJ, Nye, Shure, Cubic, Tempo, Ten-Tec and others. **Appliance & Equipment Co., Inc., 2317 Vance Jackson Road, San Antonio TX 78213, 734-7793.**

Vienna VA

The Washington metropolitan area's leading supplier of the latest in Amateur Radio and Test Equipment. On your next trip to the Nation's Capital, stop by and see us. **Electronic Equipment Bank, Inc., 516 Mill St. N.E., Vienna VA 22180, 938-3350.**

DEALERS

Your company name and message can contain up to 25 words for as little as $150 yearly (prepaid), or $15 per month (prepaid quarterly). No mention of mail-order business or area code permitted. Directory text and payment must reach us 60 days in advance of publication. For example, advertising for the December issue must be in our hands by October 1st. Mail to 73 Magazine, Peterborough NH 03458. ATTN: Nancy Ciampa.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

DARKEST AFRICA

What would *you* say if the phone rang one day and someone offered you an all-expenses paid trip to Africa . . . for two?

It was July 4th, a Saturday, and I was sitting there writing an editorial. Weekends are the only time when there are no interruptions and I can concentrate on writing, so I was annoyed when one of the phones rang. I got all over the aggravation when I found I was talking with South Africa . . . that there was going to be a microcomputer exposition in Johannesburg in a month and they wanted me to come down at their expense to address the group.

With a new magazine being launched in September, I was hesitant. We have a lot riding on the success of *Desktop Computing* and I didn't want to take any chances.

When they threw in short visits to Swaziland and Lesotho, I was hooked. With 99 countries visited so far, this would put me well over one hundred. Plus I wanted to know what was going on in South Africa as far as both amateur radio and computers are concerned and there is nothing like a personal visit.

It had been 15 years since I had been to Africa, with the exception of Egypt. In 1966, I talked some other hams into going over for a hunting safari in Kenya, using as my guide a book by Herter on how to go on safari for $660. We'd visited Kenya, Uganda, and Tanzania at the time and my impression was that all of these countries were headed away from civilization, with the latter two going back to the bush the fastest.

Sherry looked over the routing to South Africa and found that the best (lowest cost) route was via Rio de Janeiro on the way over and via Nairobi in Kenya on the way back. The overnight stop in Rio would help us to get to South Africa rested, so that was a good move. I had her add a little to the Nairobi stopover so we could see the town, visit the game park, and even get down to the south coast of Kenya, below Mombasa, for a couple days of rest on the Indian Ocean. This would give me a chance to compare Kenya of today with what I'd seen 15 years ago.

The first big hassle was getting the visas for all of those countries within a few days. This had to be done in Washington, so we brought along our passports and the reams of papers, photographs, and visa fees when we went down to meet with the new chairman of the FCC, Mark Fowler. A professional visa expediter worked hard on it and got the passports back to us at Kennedy Airport in New York just minutes before our departure. That's enough to push anyone ulcer-prone over the edge.

Just to add to the comfort and relaxation of my trip, things were coming to a head at home on Hawthorne-Green Institute, a cooperative deal with a local college in New Hampshire to teach computing using our staff and laboratory, a prospective new magazine (which had me flying to California and New York in the last few days before taking off for Africa), two other prospective magazines (more traveling), and contracts with three microcomputer firms for software development (more travel).

A call from South Africa assured me that my ham licenses had been taken care of for ZS, 3D6, and 7P8, complete with rigs to use in all three countries. The first reports were that the 7P8 was impossible, that no licenses had been issued in ages, but then at the last minute they got it through. A small plane had been chartered for the 3D6-7P8 trip.

Finally, exactly one month after that phone call from South Africa, Sherry and I were on a Pan Am plane heading for Rio and Johannesburg. We had our passports and visas, a change of clothes, lots of cameras and film, and hopes for an opportunity to help both amateur radio and computing to grow.

What would I find in Africa? In 1966, I had seen the disintegration of Uganda as a result of the transfer of power to the blacks. They had forced the white farmers to leave the country, with the result that the farms, which had been the major source of income for Uganda via their exporting of coffee, sugar, and food, had virtually gone out of business. I saw hundreds of deserted farms and little left in the way of crops. I suspect that this weakened the country and made possible the takeover by Amin a short while later.

Next they threw out the Asians, who had been running almost 100% of the small businesses and stores, effectively destroying what was left of the economy of the country. Tanzania followed a similar pattern, as discussed in detail in a book *South of the Moon*, by Lyttel. Both countries were heading rapidly away from civilization . . . back to the bush.

In Kenya, the first president, Jomo Kenyatta, kept the white and Asian infra-structure relatively intact, thus preserving the country much better than the others. When Kenyatta died three years ago, he was succeeded by President Moi and I wondered what changes I would see.

When I visited Kenya 15 years ago, there was hope for some black hams. Would there be any now? Any DXer knows that there are very few active hams in all of Africa . . . and how many of you have ever worked a black amateur in Africa? I wanted to know what the possibilities are for developing black amateurs in

W2NSD/1 ON-THE-AIR SCHEDULE NOVEMBER, 1981

Date	Band/Mode
3	15-20m Phone
10	20m RTTY
17	15-20m Phone
24	20-40m Phone

We'll be on the air 7:00-10:00 pm eastern time on the dates listed above. Look for us in the first 25 kHz of the General class portion of the band. When two bands are listed, we'll spend 90 minutes on the first band and then switch to the second.

Africa. I felt that if amateur radio is going to get the support it needs from the 57 countries of Africa, black amateurs are a must.

The flight to Brazil is much like those to Europe, only longer. You leave in the evening and arrive early the next morning, pooped. At best, I get no more than short naps on a plane. Between the frequent meals, the movies, people walking around and talking, and the crying children, there is little peace on these long flights.

One day is not enough to really see all of Brazil, let alone Rio. We arrived early in the morning to find the city heavily hazed over and went straight to our hotel and a catch-up sleep. That afternoon we visited some friends and laid the groundwork for a return visit to talk with the government in Brasilia about setting up ham clubs in the high schools.

Brazil, as you may have read in the September *Reader's Digest*, is aiming to become a high-technology country. I pointed out to them that there is a parallel between the number of hams a country has and its electronics and communications technology. Since this is no coincidence, the best way to get the needed technicians and engineers is to get amateur radio growing in Brazil . . . in the high schools.

Early the next morning we were back on a plane, headed for Johannesburg. We got in around midnight, with some delays due to the air controllers'

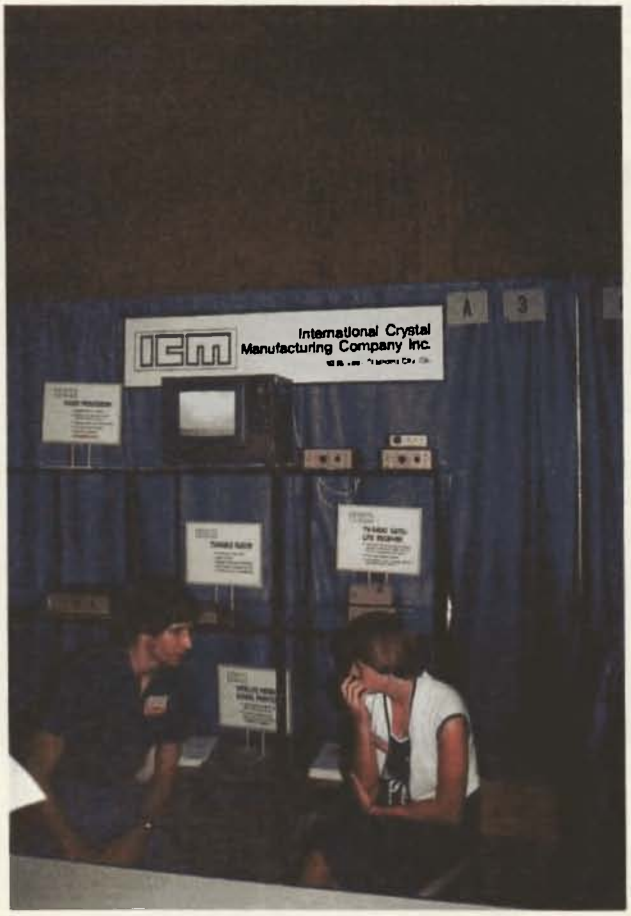
The Satellite TV Challenge

—73 Magazine's answer

Tim Daniel N8RK
73 Magazine Staff



International Crystal was one of the first firms to enter the home satellite TV market. They have expanded their line to include accessories that help make a good signal become better

Welcome to the satellite TV challenge. This issue of *73 Magazine* marks the start of a regular section devoted to the rapidly advancing TVRO (Television Receive Only) field. We at *73* are quite excited about this promising, virtually untapped, technology.

Why Satellite TV?

Hams are innovators. They make complex and expensive technology understandable and affordable. As a magazine, *73* has been in the forefront of amateur radio's innovations, first pushing solid-state gear, SSB, FM and repeaters, and, more recently, popularizing microcomputers. Along the way, *73* has shown that the spirit of ham radio is not confined to the spectrum and privileges allotted to us by the FCC. Similarly, satellite TV is more than just watching "free" movies. Don't take our word on it: read WA1DCP and W2IKQ's article, "Space Spinoffs," in this issue. There you will see that much of the pioneer work behind the home satellite TV industry has

R. L. Drake is a name that hams recognize. Their stylish TVRO receiver drew a crowd at SPTS Omaha. (See New Products section in this issue.) Drake is marketing the receiver in conjunction with another well-known amateur radio firm, Hoosier Electronics.

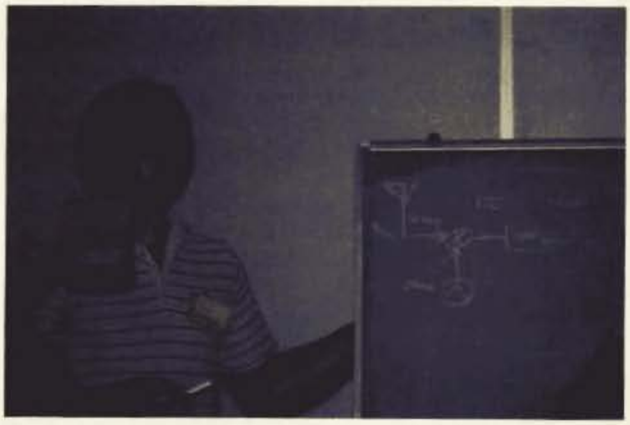
been done by hams. What does the future hold? That depends on you!

Natural Highs

Remember the thrill that accompanies the completion of a piece of homebrew gear or a kit? Or, how about the excitement each time you work a new country? These kinds of natural highs are part of the satellite TV world, too. Sure, you can spend a fistful of bucks to have someone install and debug a TVRO system. But, for a real adrenaline rush, put together your own system. When everything is finally in place and those first pictures appear after traveling 22,000+ miles, you will be *very* excited. Even then, your work is not finished. There are new satellites to find, picture quality to improve on, etc. The challenge and sweet feeling of success are waiting for you.

Getting Started

The satellite TV field is not what engineers call "steady state." You can't rely on things staying the same, nor can you expect to learn everything overnight. Getting started means a willingness to learn. There are new buzzwords to master and a new industry to become familiar with. For

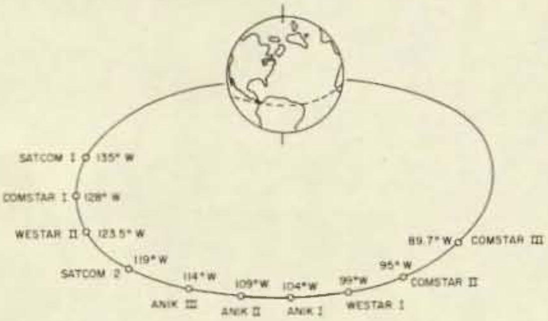


Hamfest attendees will probably recognize this smiling face. John Ramsey is the man behind the Ramsey Electronics booth. Sat-Tec, a subsidiary of Ramsey Electronics, is manufacturer of satellite receivers. John took time out at the SPTS satellite TV seminar in Omaha to share some of the secrets of designing and building low cost TVRO gear.

SATELLITE TV BASICS

Stephen Gibson
PO Box 38386
Hollywood CA 90038

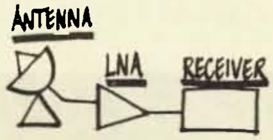
Nearly all of the TV satellites are in geostationary orbit around the Earth's equator. This belt is known as the Clarke belt, after famed science fiction author Arthur C. Clarke suggested the idea of orbiting relay stations back in the forties. The satellites are sometimes called "birds" and are located about 22,300 miles above the surface of the planet. Because they turn with the same speed as the Earth, they appear to be standing still. An antenna pointed at a Clarke orbit satellite does not have to be moved.



Geosynchronous satellites are located in the Clarke belt. This diagram includes only those birds that carry regular video programming.

The uplink is in the 5.9-to-6.4-GHz band. The mode is wideband FM video. Each satellite has either 12 or 24 transponders depending on design. Channel bandwidth is 40 MHz, but neglecting guard bands, practical bandwidth is 30 MHz. The sound is generally sent on a 6.2- or 6.8-MHz FM subcarrier. Downlink is in the 3.7-to-4.2-GHz band. Ma Bell here on Earth shares these frequencies and nearly dominates the band in metropolitan areas. Bell carriers are offset ±10 MHz from satellite carriers, so traps in the i-f can sometimes knock Ma Bell out of the picture.

The 24-channel birds use a method of frequency reuse to get the 12 extra channels. The trick is simply to send 12 channels vertically polarized and the other 12 horizontally polarized. Polarization is relative to the North Pole or the antenna skew angle on the bird and not your location.



Three-piece Earth station.

You need only three items to receive satellite TV:

1) A large dish-type antenna with a gain of 38 dB or more at 4 GHz. It depends on your geographical location and can be calculated (see "How Big a Dish?"). Surface accuracy of the dish must be within 1/8 inch to achieve any efficiency. A TV antenna rotator can be used to change antenna feed polarization. The types of antenna mounts are varied, but generally fall into two categories: polar mounts which have one turning axis and are similar to those used by astronomers, and azimuth/elevation mounts having two turning axes similar to those used by OSCAR chasers. Adjustable mounts are desirable now that several satellites have programming.

2) A preamplifier, known in the jargon as an LNA (low noise amplifier), boosts the very weak signal. It is a broadband design covering 3.7 to 4.2 GHz with 30 to 50 dB gain and a 1-to-2-dB noise figure. The GaAsFET transistors used in LNAs achieve these noise figures with ease at this frequency, but require care in handling. Careful choice of LNA noise figure and dish antenna gain are very important to receiving noise-free pictures. To avoid signal loss, the LNA is generally located at the dish antenna feedpoint which, for a parabolic dish, would be at the dish focus or focal point. A feedhorn of circular or rectangular design couples the LNA to the dish.

3) The LNA output is fed down low-loss coax to an FM receiver similar to that used by Ma Bell in the same frequency band. Sensitivity must be something around −50 to −60 dBm with a 10-to-15-dB noise figure. A received carrier-to-noise ratio of at least 10 dB will yield good pictures once the FM threshold of the receiver is exceeded. Noise or snow on the TV screen is referred to as sparklies. I-f bandwidth usually is somewhere between 20 and 30 MHz. Dual conversion is used, but single conversion designs are gaining in popularity. Subcarrier detectors recover the FM sound. The sound and video outputs of the receiver can feed a TV monitor, your VTR, or a modulator to get the signal into VHF or UHF for your TV receiver.

an introduction in a nutshell, read Stephen Gibson's "Satellite TV Basics," included here. From there you might want to tackle "How Big a Dish?", also included in this issue. All of this is just a fraction of the information we hope to bring to you via the pages of *73*. Whether you want to dive right in or just ease into the satellite TV challenge, we'll be here to show you the way.

What Good Is It?

Satellite TV can be more than just a technical toy. A TVRO system is a great way to educate and entertain your family. There are hundreds of hours of top-quality, commercial-free television available each week. For a glimpse at what satellite TV offers, see the "Satellite Channel Guide" in this issue. While there are important legal issues to consider, don't be put off by someone that says a home satellite receiver is illegal. That just isn't so. In a future issue we will have an in-depth look at the legal issues surrounding satellite TV.

Opportunity Knocks

Don't be surprised if you see a lot of familiar-looking names associated with the satellite TV industry. A recent satellite TV seminar and trade show in Omaha, Nebraska, was almost like a hamfest, with companies like R.L. Drake, KLM, and Wilson exhibiting the latest in home satellite gear. Individual hams and manufacturers are finding a lucrative market in satellite TV. Like any other growing field, it takes initiative to make it, but the opportunities are there. (For an intense three-day exposure to the commercial and technical aspects of home satellite TV, consider attending the next Satellite Private Terminal Seminar, sponsored by STTI, Box G, Arcadia OK.)

73 Magazine's coverage of the satellite TV challenge is not possible without your help. A key ingredient to our efforts is advertising. Please tell manufacturers "I saw your ad in *73*." Another reader responsibility involves filling out and returning the Reader Service card that accompanies each issue.

If you are working on something new, please take the time to share your knowledge with all of us. Input in the form of articles, product reviews, and ordinary letters is welcome. You can be sure that we will carefully consider your comments, but it may not be possible to answer all correspondence directly. ■

Space Spinoffs for Amateur Radio

—the makings of a communications revolution

Portus C. Barlow WA1DCP
Downlink, Inc.
30 Park Street
Putnam CT 06260

Wes Thomas W2IKQ
606 Fifth Avenue
East Northport NY 11731

Revolutionary changes in amateur radio may be on the way. With the cost of backyard TVRO (television receive only) systems plummeting and the telecommunications industry gearing up for rooftop data and video business communications, new forms of space-age amateur radio communications are becoming feasible. Here are some of the mind-boggling possibilities:

- National or global two-way amateur satellite communications, 24 hours a day.
- Dramatically improved moonbounce communications, using low-cost TVRO dish antennas at microwave frequencies.
- And national packet-switched microwave-linked repeater networks for voice, electronic mail, and information-bank access.

Right now, there's over 1100 MHz of amateur spectrum to work with, virtually unused (see Fig. 1). And that

73 Magazine publisher Wayne Green W2NSD discusses the ham radio, satellite TV tie-in with Portus Barlow WA1DCP, president of Downlink.

1215-1300 MHz*
2300-2450 MHz
3300-3500 MHz*
5650-5925 MHz*
10-10.5 GHz*
24-24.25 GHz*
***Satellite operation permitted on part or all of band.**

Fig. 1. Practical microwave amateur bands.

doesn't include the 31 GHz allocated above 24 GHz. Best of all, there is great promise for low-cost equipment becoming available for the bands between 1 and 24 GHz.

What equipment, you ask? Well, consider the mountain of gear available for 3.7-to-4.2-GHz satellite TV reception. Many hams have this equipment sitting in their backyards already, aimed at one of the eleven domestic (US and Canada) satellites. Hams already have played a key role in the TVRO technology that has exploded since Bob Cooper W5KHT "went public" in *TV Guide*. Here are some of the key developments:

- Bob Coleman K4AWB's plans for converting surplus microwave equipment.
- Oliver Swan's revolutionary low-cost "window screen" spherical antenna, capable of capturing signals from several satellites.
- Taylor Howard W6HD's low-cost, do-it-yourself TVRO-receiver design.
- Bob Luly KA6KBU's 22-pound, 12-foot, portable umbrella antenna.
- Steve Gibson's microcomputer-controlled antenna.
- Clyde Washburn's 24-channel, tunable TVRO receiver.

The result of all this innovation: under-$4000, consumer-TVRO systems. For an idea of what the future might hold, see the box.

"The next logical step is to start working on low-cost uplinking," says Stanford University Professor Taylor Howard. Let's take a look at how this might proceed. Right now, 1296 MHz seems to be the frontier, with just a handful of pioneers using the band for EME (moonbounce). Steve Mieth W6YFK, for example, is achieving EME echo with an 18-foot TVRO-style parabolic antenna, 80 to 100 Watts into the feed, and a preamp with a 1-dB noise figure. This sure beats those monster two-meter arrays and 1-kW rigs! Steve also has had some success on 2300 MHz with a similar setup. The 2300 band is interesting because of the dozens of companies manufacturing MDS receivers, as well as the surplus gear that is becoming available. Dxers with an eye on the 2400-MHz band may get a chance to try their hand at receiving signals from the UoSAT satellite, scheduled for launch this fall.

"The mystery is out of microwaves."

Another interesting band is 3.4 to 3.5 GHz which falls right below the 3.7-to-4.2-TVRO band. We could easily adapt low-cost TVRO low-noise amplifiers and antennas for this band, to say nothing of all that surplus Ma Bell and military gear available. Combine those possibilities with the 5.65-to-5.925-GHz band, which falls just below the 6-GHz uplink band. Power GaAs FETs and other transmitting devices are becoming available, so we theoretically have the basis of a full-blown amateur satellite communications system.

Consider this, again theoretically: Two Watts into the standard 12-foot-TVRO antenna is sufficient to communicate via a geostationary satellite with a 4-kHz-wide signal. For a full 36-MHz-wide video signal you'd need about five kilowatts.

That suggests some interesting possibilities. Why not lease a preemptable 4-kHz subcarrier on a commercial satellite? Think of it as a repeater with *very* good range! Say, the entire US, Canada, and Mexico! To keep things under control, an encryption circuit could be built right into the transponder receiver. This would allow the common carrier (RCA, Western Union, etc.) to shut out amateurs when the circuit was needed for another customer.

And what about the world of GHz and above? Hams are there experimenting, too, thanks to the commercial availability of Gunnplexers. The coming race for direct-broadcast satellite services will spin off some great equipment! Hams are already at 24 GHz during contests.

Taylor Howard W6HD offers some interesting thoughts about the specific developments that are in store for amateur radio. He sees antenna feed design, lower cost detectors, and microwave-frequency filtering on PC boards as key areas. On the uplink side, W6HD believes we need to develop low-cost solid-state amplifiers, high-stability multiplier chains, and inexpensive synthesizers. "The mystery is out of microwaves," Howard says, "and hams are the ones who will pioneer low-cost uplinking."■

Satellite TV net hams interested in satellite TV have been gathering on 20 meters, 14.310 MHz, starting at 1900 UTC on Sundays.

What's Next?

Here's a sneak preview of what's coming in home satellite TV. Watch for:

- A $350 electronically-switched polarization device, eliminating need for mechanical rotation of the feed horn.
- An easy-to-build, complete TVRO pre-packaged kit for under $2,000.
- Microprocessor-controlled dish antennas and receivers for satellite selection and tracking, and transponder scanning and selection, all tied in with programmable VTRs.

Stephen Gibson enjoys both computers and Earth stations.

Stephen Gibson
PO Box 38386
Hollywood CA 90038

eginning this month, I will cover the principles of satellite TV with an eye on details on how you can design and build or buy your own Earth station. In the months that follow, I will continue with the basics of each element of your TVRO (television receive only) terminal. I hope that this series, Satellite Central, will become a conduit for ideas and developments that will make construction and operation of your Earth station much easier.

I also hope to include satellite technical info and some program information of interest to add to the fun. There is more than just TV up on the satellites and we will cover every aspect in some detail so you can pursue your own brand of DX from the sky. This is an exciting new way for you to liven up your communications hobby because everyone around you can appreciate your efforts.

How Big A Dish? (Not All Locations Are Created Equal)

It seems appropriate to start off our discussion with antennas. Because the received-signal levels are very weak, we need rather high antenna gains. How much gain is needed? Good question. It works out that "where you are" is everything. Most of the birds with TV on them do not employ global-coverage antenna patterns. In fact, they are quite selective. Signal levels vary several dB over the continental United States.

Satellite designers predict the coverage patterns as "footprints" on a map. Fig. 1 is a footprint map for expected signal intensities from SATCOM 1, a very popular cable-TV bird. Despite the accuracy with which we can steer a *Voyager* probe into orbit around Saturn, we can predict only within a couple of dB or so what the signal level footprints will actually be. You may think that's very good (and it is), but it can make a big difference in your antenna (pocketbookwise) as we shall soon see.

Footprint Tracking Made Easy

The numbers on the map are signal levels in dBW (decibels above 1 Watt). They look pretty substantial. But the satellites are about 22,300 miles away, so there must be some loss. It works out to about −196 dB at 4 GHz. Using the center of the footprint, for example, where the power level is +36 dBW, the signal arriving here on Earth is really −160 dBW (+36 − 196 = −160 dBW), and that's weak! In fact, it's so weak that we don't have a receiver sensitive enough to get it! A typical TVRO receiver needs something like −80 dBW to work.

So we need gain and lots of it. Only one problem. The awful truth is that a yagi (even at Radio Shack specs) or a whole array of yagis don't have enough gain even if you could get them all to operate in phase. The antenna array needed to meet the receiver requirements would be gigantic and probably cost more than next year's national debt!

So why not add a preamp? Fine, but yagi antennas and the like also pick up terrestrial noise and a preamp won't make the noise go away; it'll just make it louder. Dish-design antennas are perhaps a better choice because they offer more gain per area/cost and they have narrow beamwidths which means they don't see as much noise. Table 1 is a list of practical antenna sizes and their gains.

6 feet	35.0 dB
8 feet	37.5 dB
10 feet	39.5 dB
12 feet	41.0 dB
15 feet	42.9 dB
20 feet	44.5 dB

Table 1. Typical dish antenna gains at 4 GHz based on diameter. These values can vary based on the efficiency of your feed arrangement and dish accuracy.

Note that a 20-foot dish has only about 44.5 dB gain, but we need 80 dB gain. Looks bad, doesn't it? So we're back to adding a preamp.

New problem. The preamp must have an excellent noise figure. In fact, the preamp has a special NASA-type designation called LNA, which is simply "low noise amplifier." It appears that we must somehow have enough antenna gain to overcome the incoming terrestrial noise and the noise generated by the LNA.

Noise is the Culprit

If we could find a place in the universe where there was no molecular activity we'd have a very quiet place. It would also be very cold. Radio astronomers use a scale known as the Kelvin scale to measure noise temperature in the sky. Zero degrees on the Kelvin scale is roughly some 273 degrees *below* zero degrees on the Centigrade scale. If we think of zero degrees Kelvin as zero activity and noise, then we have an absolute scale to measure noise in our system.

Typical sources of noise that can bother our TVRO

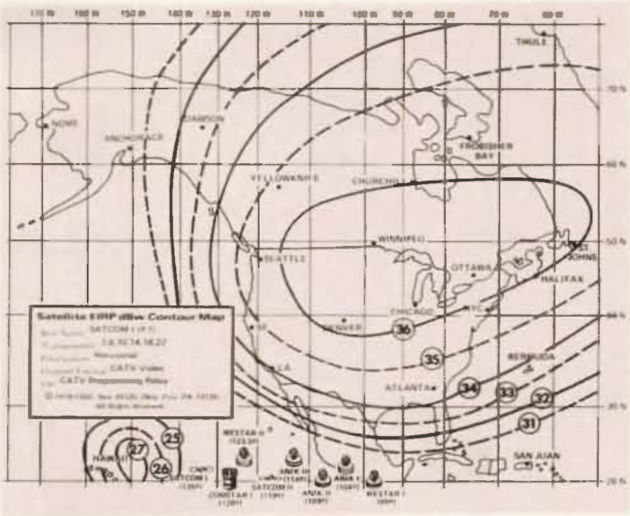

Fig. 1. Use this footprint map of antenna coverage patterns from SATCOM 1 to calculate the received signal level at your location. SATCOM and COMSTAR satellites have three other footprint patterns including this one for all 24 transponders. WESTAR and ANIK birds use a single pattern for all 12 transponders. WESTAR III, not shown, is at 90.0°.

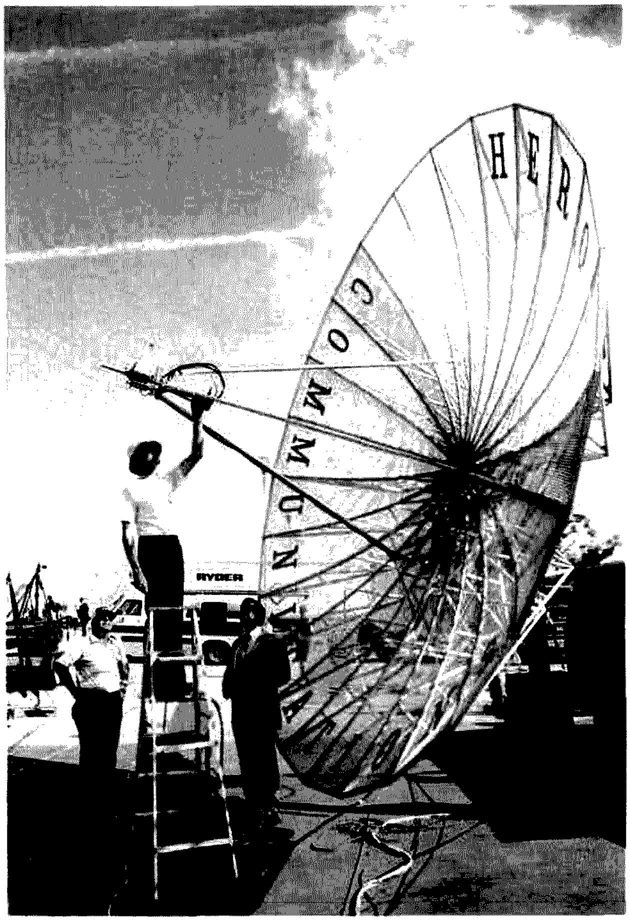
Getting from here to there with a dish antenna requires some ingenuity. This is one company's answer to the problem.



An antenna shootout was featured at SPTS Omaha. It proved that all antennas are not created equal. Tests by two impartial engineers gave both manufacturers and buyers a chance to see which antennas were up to snuff.

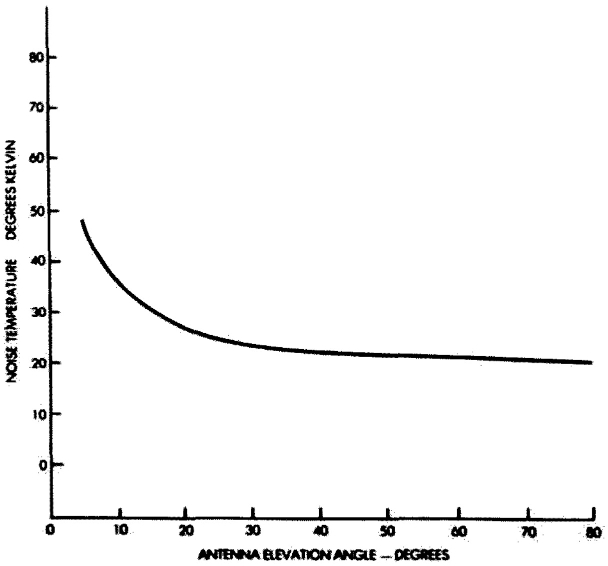


Fig. 2. Even large dishes intercept terrestrial noise, but the noise level drops as you tilt the dish back from the horizon towards the open sky. Typical dish angles for Clarke orbit birds may be from 20 to 60 degrees depending on your location.

are rain, the sun, other microwave services, and the Earth itself. In fact, the noise temperature of the Earth is about 290 degrees Kelvin.

Perhaps you've guessed that we need an antenna with enough directionality to ignore terrestrial noise. System designers express this as a ratio of carrier-to-noise, or C/N. As a rule, most receivers need a C/N ratio of about 10 dB. That is, the received carrier must be 10 dB hotter than the noise to get clear pictures. So all we really need to know is the satellite signal level at our location and the noise level. If we add 10 dB to the difference we should have the required antenna gain.

Simple Dish Math

We use this formula to calculate noise level: Noise Power = KTB, where K = Boltzman's constant, 1.38×10^{-23}, T = system noise temperature, and B = system bandwidth.

How do we use it to get a right answer? (All too often, you see a formula and plug in some sample numbers and voila . . . wrong answer!) Here are the exact steps to take. First, we see that the typical bandwidth of satellite TV signals is 30 MHz. A quick look at the above formula may cause you think if you could reduce the bandwidth a little, you could also reduce the noise. The question is, how much can we cut before the picture looks rotten? I'll cover that in another installment.

A noise figure of	equals a noise temperature of
290° K	3.0 dB
225° K	2.5 dB
170° K	2.0 dB
120° K	1.5 dB
100° K	1.3 dB
75° K	1.0 dB

Table 2. LNA noise temperature to noise figure conversion.

Next, we must know the system noise temperature. This is a mixture of antenna noise, LNA noise, and receiver noise. Inasmuch as we must surpass the noise threshold of the receiver by at least 10 dB, we can ignore receiver noise temperature and just deal with the antenna noise and LNA noise. Fig. 2 is a graph of typical antenna noise temperatures based on elevation angle. Notice that the noise appears to drop as we tilt the antenna back from the Earth towards the open sky.

Table 2 is a list of typical LNA noise temperatures you are likely to find. As of this writing, 100 degrees is considered a very good LNA for the money. That may change. If we now add the LNA noise temperature to the noise intercepted by the antenna we have a fair idea of the system noise temperature. For example, an antenna tilted back to 45 degrees elevation might intercept 20 degrees Kelvin noise. Suppose we chose a 100 degree LNA. Adding, we get an overall noise temperature of 120°. Then all we do is use the formula, Noise Power = KTB.

$1.38 \times 10^{-23} \times 120° \times 30 \times 10^{6} = 49 \times 10^{-15}$. Converting to a power ratio: Noise in dBW = 10 Log (Noise Power) = −133 dBW.

If you've managed to stay with the numbers so far, you can see that the signal from space (−160 dBW) is *weaker* than the noise level (−133 dBW). But if we add in some antenna gain—say 40 dB or so—we boost the signal from space up and out of the noise to −120 dBW: −160 dBW + 40 dB dish = −120 dBW signal level.

Then subtracting: −120 dBW (Noise) − (−) 133 dBW (Signal with antenna) = 13 dB C/N. The satellite signal exceeds the noise level by a robust 13 dB, giv-

ing us solid copy picture-wise.

Easy Formula Saves Time

To find the antenna gain you need for your particular location, you simply apply Gibson's Dish Antenna Rule: Antenna Gain = Noise Level − Signal Level + C/N.

Using our example figures: −133 dBW (Noise) − (−) 160 dBW (Signal) + 13 dB (Suggested C/N) = 40 dB dish! Based on the table of dish antenna gains, it looks as if an 11- or 12-foot dish would work . . . but only if we use a 100 degree LNA.

Try It For Your Location

All you really need to calculate the right dish size for your spot on the map is a footprint map and the two formulas above. If your location does not fall on a particular contour on the map, then do some interpolation and estimate. If anything, estimate lower than the map. Remember, we said the footprints were predictions and actual values have been found to vary a couple of dB.

Next, subtract the path loss of 196 dB. Then figure the noise level based on the LNA you've chosen and the 3-dB bandwidth of your receiver. Plug the numbers into Gibson's Dish Antenna Rule and hope the dish gain needed fits your pocketbook. If it looks as if you'll need to buy an acre of real estate for your giant behemoth, then try a lower LNA noise temperature or a receiver bandwidth of, say 22 MHz, and plug in the numbers to find the dish gain again. Just remember that you may need to hock the family jewels to buy a super-duper LNA.

Perhaps you see that the antenna and LNA are on a kind of teeter-totter. Bigger dishes mean you can use an LNA with a higher noise temperature; a smaller dish means you need a lower noise temperature LNA along with a higher price tag. We can resort to graphs to put the dish cost vs LNA cost ratio in perspective, but costs on LNAs are dropping like flies as are some antenna prices. Maybe you could see it better as: Gibson's Simple Path Loss Equation: Big Dish + Good LNA = Clear Pictures.

But that all seems obvious now. Instead, let's apply Clever Idea #1: Big Dish + Not So Good LNA = Good Pictures. Or we could also apply Clever Idea # 2: Not-So-Big Dish + Good LNA = Good Pictures.

You are free to experiment with the values and see the interaction. Maybe you'd like to write a computer program to translate your ideas via the formulas into a complete line-equation program. As a TVRO entrepreneur, this would be a nice bell and whistle for potential customers.

Satellite Central needs your input of comments and ideas, with full credit to be given, of course. The time is right for you to join in the fun of receiving TV from space. If you have a question regarding the topics we cover here, feel free to drop me a line (letters only, no calls please). Sorry, I can answer mail only if it is accompanied by an SASE.■

Satellite Channel Guide
—part I

RCA SATCOM 1 (135°W)
Polarization: ODD—Vertical; EVEN—Horizontal

TR—1	Nickelodeon—premium children's programming (6.8) ARTS (Alpha Repertory Television Service)—performing and cultural arts programming (6.8)
TR—2	PTL (People That Love)—religious (6.8)
TR—3	WGN-TV, Chicago—Midwest's leading independent station (6.8)
TR—5	The Movie Channel—24 hr/day first-run movies (6.8)
TR—6	WTBS, Altanta—Ted Turner's Superstation
TR—7	ESPN (Entertainment & Sports Network)—24 hr/day sports (6.8)
TR—8	CBN (Christian Broadcasting Network)—religious (6.8)
TR—9	C-SPAN—live coverage from the House of Representatives (6.8) USA Network—professional sporting events, Calliope, and the English Channel (6.8) BET (Black Entertainment Network) (6.8)
TR—10	Showtime (West)—first-run movies, entertainment specials (6.8)
TR—11	MTV (Music Television)—Pop/Rock Video (5.8 & 6.62 stereo)
TR—12	Showtime (East)—first-run movies, entertainment specials (6.8)
TR—14	CNN (Cable News Network)—24 hr/day news (6.8)
TR—15	Occasional Transmissions—sporting events, news & network feeds (6.2/6.8)
TR—16	Showtime (Spare)—occasional network remote and sports events feeds (6.8) AETN (American Educational Television Network) (6.8) CMN (Christian Media Network)—religious (6.8) NJT (National Jewish Television)—religious (6.8)
TR—17	WOR-TV, New York—the Big Apple's top independent station (6.8)
TR—18	Reuter's Monitor Service—commodity/stock market information (digital video) Galavision—the best in Spanish-oriented programming (6.8)
TR—19	The Shopping Channel—Shop-at-Home TV service (6.8) Spotlight—first-run movies (6.8)
TR—20	Home Box Office Cinemax (East)—time-structured HBO (6.8)
TR—21	HTN (Home Theatre Network)—quality P and PG movies (6.8) The Weather Channel (est. Spring 1982)
TR—22	HBO (Home Box Office) (West)—first-run movies, sports & entertainment specials (6.8) MSN (Modern Satellite Network)—general entertainment (6.8) Beta—programming for women (est. 1-4-82)
TR—23	HBO Cinemax (West)—time-structured HBO (6.8)
TR—24	HBO (East)—first-run movies, sports & entertainment specials (6.8)

Audio Services on SATCOM 1

Satellite TV Receivers

— is there a better way?

Dave Ingram K4TWJ
Eastwood Village #1201 South
Rte. 11, Box 499
Birmingham AL 35210

My original review of the Universal Communications 2300-MHz downconverter kits, which appeared in the April, 1981, *73 Magazine*, revealed the widespread interest in receiving MDS and commercial TV satellite transmissions. Indeed, my mailbox bulged with letters for several weeks after the article was published.

A large number of inquiries received concerned my briefly-mentioned thoughts of later converting a Universal Communications unit (or some semblance thereof) for reception of the 3.7-to-4.2-GHz satellite TV band, and (hopefully) assembling a complete but inexpensive TVRO system.

This article on TVRO is written to share my work and knowledge, plus the work of Steve Franklin of Universal Communications, with others desiring infor-

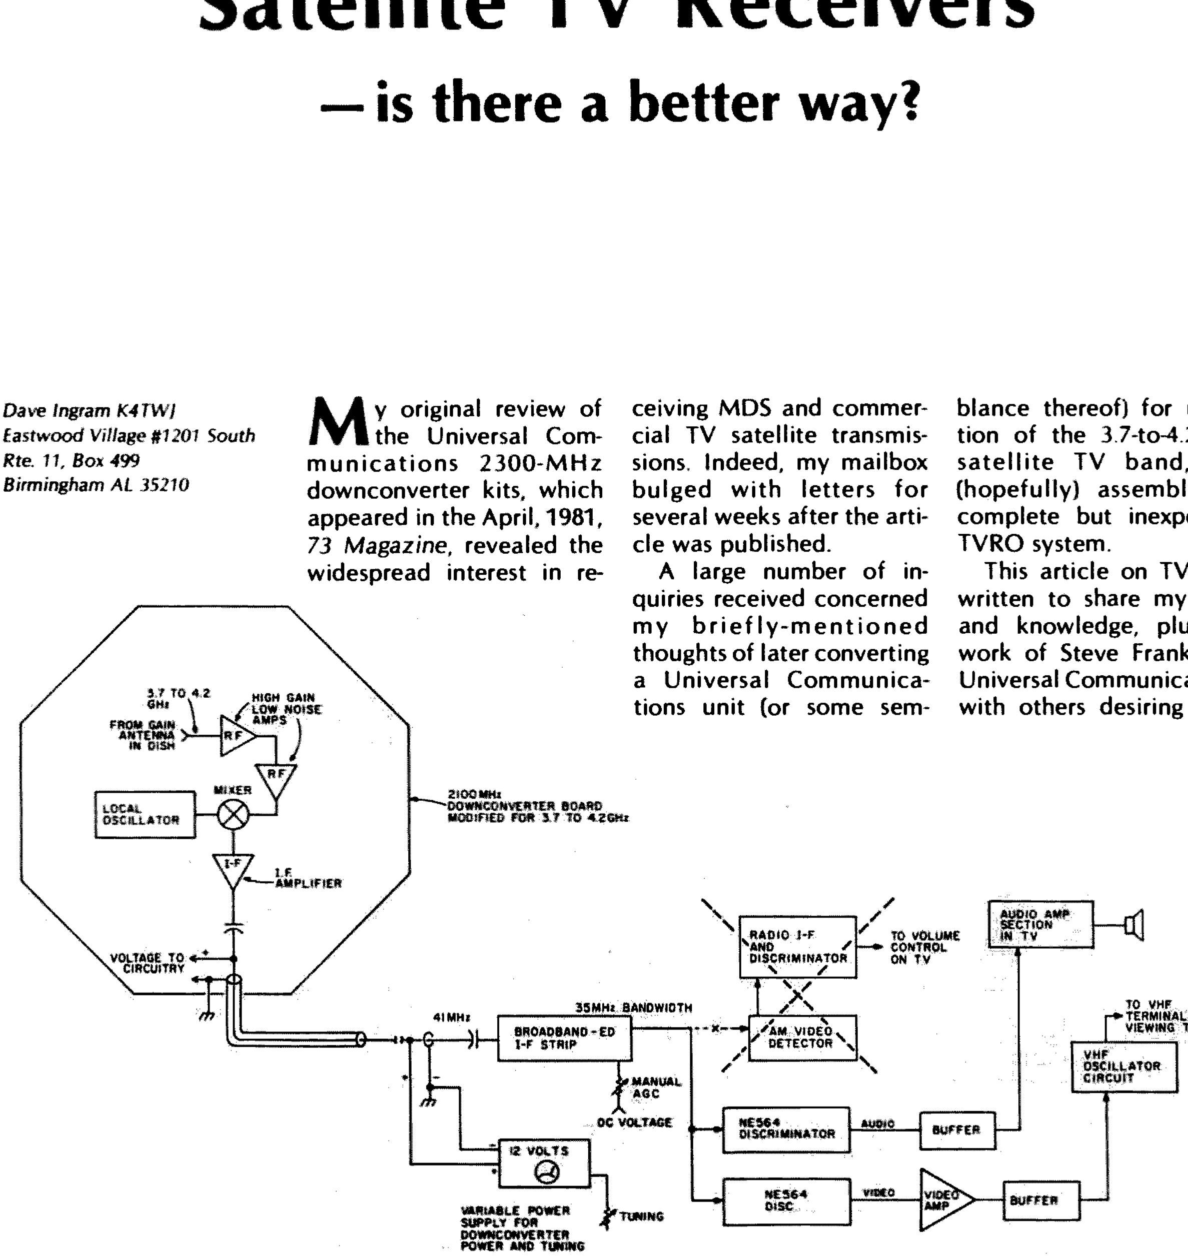

Fig. 1. The originally-planned TVRO described in the text. The 2100-MHz downconverter board is modified by cutting tuned lines to approximately half length, adding two high-gain, low-noise transistors, low-noise diodes, generating 41 MHz i-f, etc. Highly-modified televison is used mainly for its i-f strip, power supply, and audio amplifier section.

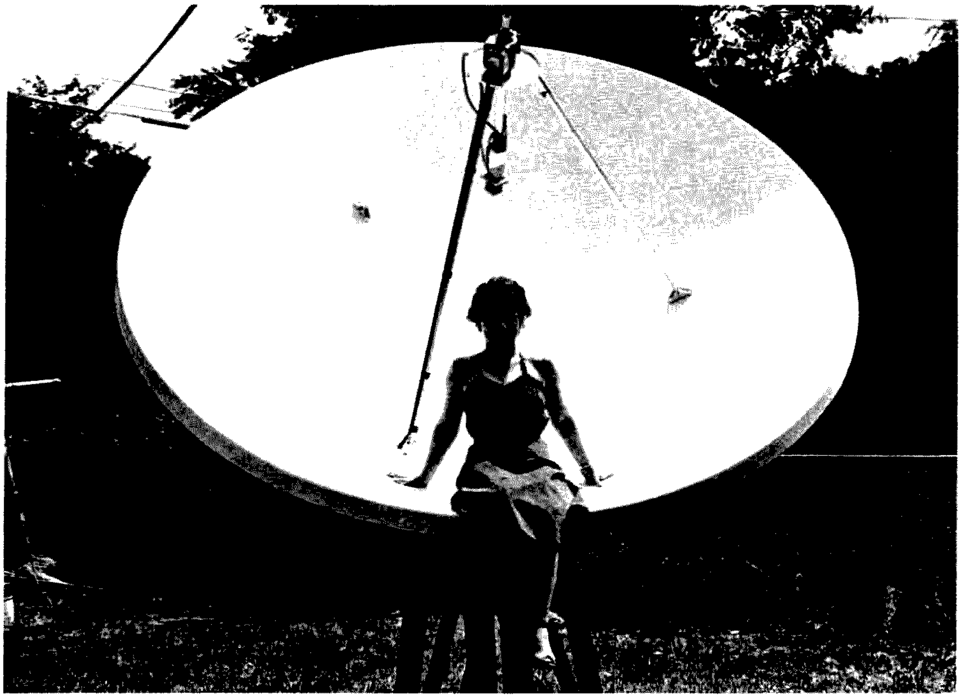
mation on TVRO designs. Perhaps I'll answer some questions that you've been pondering, or possibly I'll whet your thoughts on simpler and less-expensive ways of constructing TVROs. An excess of knowledge and concepts in this area of rising popularity is one thing we aren't experiencing at this time!



Deborah Franklin tries on a 10′ parabolic dish fitted with an Avantek LNA and 3.7-to-4.2-GHz downconverter described in the text.

The Originally-Planned Concept

Most of the presently-popular commercial TVRO systems employ a basically similar design: A high-gain, low-noise amplifier (LNA) is placed at the focal point of a 10- to 16-foot parabolic dish which is aimed at a specific satellite. The acquired signals then are fed to an indoor converter unit via hardline cable. That unit converts incoming frequencies between 3.7 and 4.2 GHz to the popular TVRO i-f frequency of 70 MHz, amplifies the signal, and detects the FM video and 6.2- or 6.8-MHz audio (depending on the particular satellite being received). The resultant baseband signals then are used to modulate a TV oscillator circuit which radiates into the TV set's VHF antenna terminals. Selecting various transponders of a satellite is accomplished by varying the indoor tuner's selected input frequency and downconverting that channel to the 70-MHz i-f range.

While the previously described concept is an optimum turnkey system, it seems that an enterprising amateur could shave frills and lower system cost with a different approach to TVROs. The hardline cable connecting the LNA to the tuner, for example, exhibits a typical loss of 15 dB—part of the gain provided by the LNA. It thus seems that if a low-noise figure could be obtained, a home-brew rf amplifier/tuner unit could be mounted at the dish and used to downconvert with techniques similar to those used in inexpensive 2400-MHz MDS converters. The resultant 35-MHz bandwidth i-f signal might then be processed by a highly-modified black and white TV (nothing dictates the use of a 70-MHz i-f).

Such TVs usually can be obtained from repair shops or friends (sets with bad picture tubes or flybacks are good candidates for this operation). The downconverter's output cable would sidestep the TV tuner and connect directly to the i-f input. The i-f stages would then be heavily swamped and stagger-tuned to increase bandwidth from near 5 MHz to near 35 MHz (additional i-f stages also might be required here). The AM video detector then would be replaced with a broadband FM counterpart, such as an NE564 discriminator chip, while another NE564 tuned to either 6.2 or 6.8 MHz would be used for audio demodulation.

A small TV oscillator circuit then could be home-brewed or obtained from a surplus outlet and used to feed the satellite TV signal to the antenna terminals of an unbutchered (and usually color!) TV set for viewing. The complete receiver is shown in Fig. 1.

The Universal Communications 2.1-GHz MDS receiver might be a candidate for a low-cost downconverter. The rf amplifier would have to be replaced with a low-noise, high-gain counterpart while the mixer and oscillator circuits would need to be trimmed to the new frequency range.

The greatest drawback to

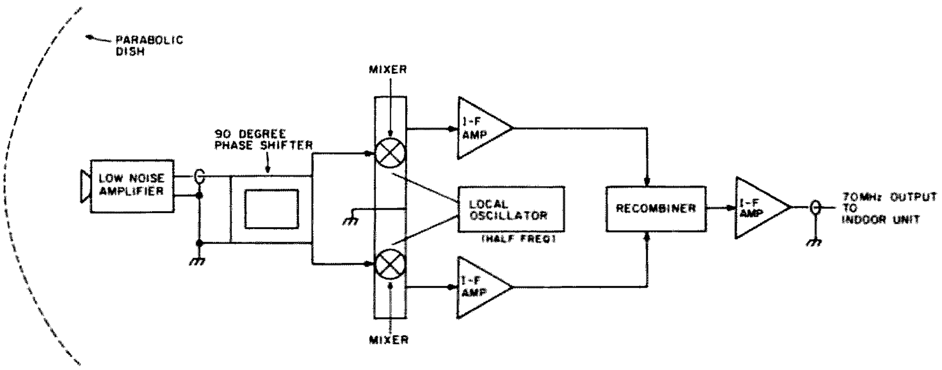


Fig. 2. The Universal Communications 3.7-to-4.2-GHz downconverter. The unit incorporates dual mixers operating 90 degrees out of phase and dual i-f amplification.

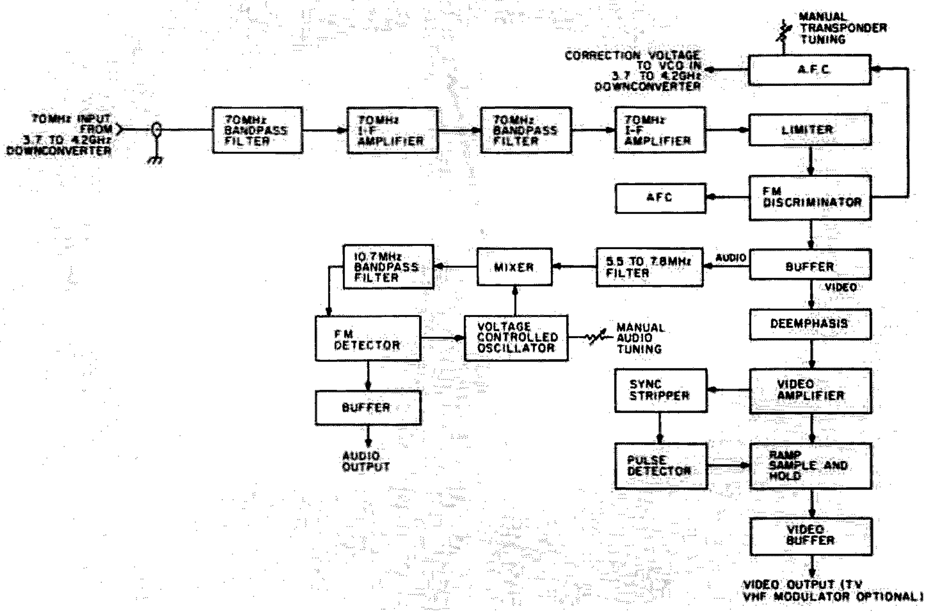

Fig. 3. Block diagram of the indoor tuning unit. Circuitry is straightforward, with video sampling similar to SSTV techniques being employed.

this scheme, shown in Fig. 1, may lie in the cumbersome modification of the downconverter and TV set. The price is right but the patience and expertise required are probably beyond the average hobbyist. Steve Franklin has shown that pictures can be received with such a system, but they are plagued by noise and image problems. The receiver that grew out of this approach uses a conventional low-noise amplifier and a doubly-balanced mixer, eliminating many of the problems that plague simple receivers.

Finally, an i-f section consisting of a few ICs, etc., plus FM discriminators for audio and video, were required to round out the system.

The Universal Communications Concept

A block diagram of the resultant Universal Communications 3.7-to-4.2-GHz downconverter is shown in Fig. 2, and a brief description of its operation follows. First, the LNA is an Avantek unit, GaAsFET, 4 stages, with 50-dB overall gain and a 120° Kelvin noise figure. The LNA cost (in July, 1981) is $650. Signals from the LNA are applied to the downconverter's 90° phase shifter, producing the two out-of-phase signals for application to their respective mixers (these mixers are similar to those used on 2.1-GHz downconverter boards).

The mixers are fed from a common local oscillator operating at half the desired frequency (this board-mounted oscillator is substantially less expensive than standard TVRO types). Outputs from the two mixers are then amplified to overcome phase-shift losses, applied to a recombiner, and followed by an additional stage of i-f amplification. The output signal is then passed to the indoor unit via a length of RG-59 coaxial cable. The downconverter, incidentally, could be mounted inside if desired, but hardline coax then would be required for interconnecting runs over 25 feet.

The TVRO unit placed inside the house functions in a straightforward manner: Its block diagram is shown in Fig. 3, and a description of its operations follows. The incoming 70-MHz i-f signal first undergoes a series of bandpass filters and i-f amplifiers before being applied to a limiter stage and an FM discriminator. The detected signal then is directed to a buffer stage which splits it and feeds two points. Following along the video path first, the signal undergoes de-emphasis and then is applied to a video amplifier which includes positive or negative video polarity output.

Next, a video sampling arrangement similar to more sophisticated SSTV techniques is employed: A sync stripper, pulse detector, and a ramp sample-and-hold circuit produce high-quality video outputs. These video levels then are buffered and applied to a VHF TV modulator which connects to the viewing TV via its antenna terminals.

Returning to the FM discriminator, satellite TV audio is bandpass-filtered and applied to an afc-locked converter and detector. This section consists of a voltage-controlled oscillator (vco), mixer, 10.7-MHz bandpass filter, FM detector, and an afc circuit. Simply described, this "closed-loop" system's afc monitors the FM detector's output and directs a proportional correction voltage to the converter's vco as required. An additional voltage input is employed for manual tuning of the audio. The output audio signal then is handled in a conventional manner.

As this article is being written, Universal Communications (PO Box 339, Arlington TX 76010) is gearing up to produce TVROs based on the previously-described concept. This arrangement definitely has broken the price barrier (*projected* cost, less dish and LNA, is $800!) while maintaining the quality of equivalent systems selling for over $1500. Its design is the most logical approach to satellite TV receivers I've seen, and I heartily recommend considering its concept. The question of system kits is presently unresolved, due primarily to problems encountered with home constructors "botching up" the simple MDS downconverters also manufactured by Universal Communications.

Summary

Satellite TV reception is a rising trend which promises increased popularity during the near future, and now is an opportune time to join that activity. The equipment capable of receiving weak microwave signals from these satellites is necessarily expensive: That restricts general-public reception and provides a measure of "cloaking" to the satellite signals. While home-brew TVROs can't sidestep the high costs of LNAs, GaAsFETs, etc., the contemplation of such setups gives one a relatively good understanding of the circuitry involved and a better overview of what he's getting for his money. ■

Spread Spectrum
—a report from AMRAD

Editor's Note: Until recently, spread spectrum has been a term known only to a tew people involved in developing top-secret military communications. Today, the possibility of using spread spectrum for other radio services is being investigated by a group of radio amateurs known as AMRAD, Amateur Radio Research and Development Corporation. After receiving a Special Temporary Authority from the FCC, AMRAD pushed ahead to try spread spectrum on the amateur bands. AMRAD members are interested in experimental communications systems of all types. Membership is available to any interested person for $12 a year. This includes a subscription to the club newsletter. To join AMRAD, contact Gerald Adkins, Treasurer, 1206 Livingston St. North, Arlington VA 22205. • The following article is based on material appearing in the July, 1981, issue of the AMRAD newsletter.

The term *spread spectrum* has been used to describe a variety of communications techniques. The common feature of these systems is that a spread-spectrum (SS) signal has a bandwidth that is much wider than the bandwidth of a conventional signal carrying the same information. At first glance, spread-spectrum communications appear to waste valuable frequency space. In reality, SS offers several very important advantages over conventional amplitude- or frequency-modulation methods.

The military likes spread spectrum because it is very secure. You can't eavesdrop on a spread-spectrum conversation if you don't know the sequence used to code the signal. Another tactical advantage offered by SS is its immunity to jamming. Unless the enemy has a very wideband transmitter, he won't do much harm to your signal.

A similar sort of immunity exists for unintentional interference (QRM and QRN). The SS signal is also likely to resist selective fading that affects one channel. In the past, diversity-receiving techniques have been used to combat fading; now, spread spectrum offers hope.

Although a spread-spectrum signal takes up a large bandwidth, the spectral density is much lower than a narrowband signal. The same information is there; it's just spread over more spectrum. This opens up the possibility of a large number of SS signals sharing a band. Or perhaps spread spectrum can peacefully coexist with narrowband signals.

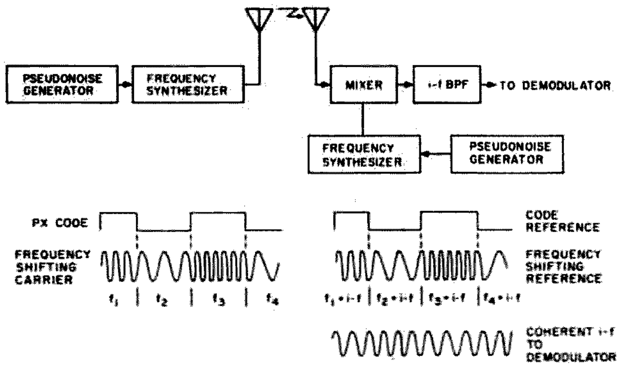

Fig. 1. Basic frequency-hopping system with waveforms. (from "Potential Use of Spread Spectrum Techniques in Non-government Applications.")

There are several types of spread-spectrum communications being used today. The AMRAD experiments are focusing on the frequency-hopping and direct-sequence techniques. This report will focus on the frequency-hopping project in particular: the use of commercial SS units on the 80-, 40-, and 20-meter bands. We won't go into much detail on the inner workings of frequency hopping; for more information, Rinaldo's article in the November, 1980, issue of *QST* and the FCC report, "Potential Use of Spread Spectrum in Non-Government Applications," are recommended. The FCC report is available from the National Technical Information Service, Springfield VA 22161. The accession number is PB81-165-284. The cost is $17 paper, $3.50 microfiche.

Frequency hopping is just what the name implies: The transmitter's carrier frequency jumps from channel to channel. The receiver follows along, in the same pattern. To keep the information secure, a frequency-hopped signal spends very little time on one frequency before moving in what appears to be a random manner. Fig. 1 shows a simple frequency-hopping system.

Experiment #1

We had a series of very successful frequency-hopping experiments carried out by Paul Rinaldo W4RI, Dick Kessler K2SZE (in Rochester, New York), and Olaf Rask WA3ZXW (in Annapolis, Maryland). Experiment #1 of the AMRAD Special Temporary Authority (STA) called for tests with a commercial/military frequency hopper in the 80-, 40-, and 20-meter bands. These rigs are capable of a frequency range of 2 to 15 MHz and hopping speeds adjustable from about 1 hop/second (1 chip, for you units buffs) to about 20 hops/second. The hopping sequence was assumed to be nonlinear because this rig was meant for military purposes. Normal linear sequences of short duration

are not useful for military applications.

Using these rigs is somewhat different from a standard single-sideband transceiver, but enough of the operations are the same that an amateur would feel right at home with this mode. I was able to sit in on a session that Paul had one evening and will describe what I heard.

First, both stations made contact using SSB (this was on 75 meters) on a service frequency. The next major item was making sure that the hopping-sequence generators on both rigs were set the same way. The rig has a set of thumbwheels on the front panel which are used to control the hopping sequence. Both stations set the wheels the same way. If the wheels had been set differently, the hopping sequences would be different, and the two stations couldn't talk to each other.

Now that the hopping sequences were set the same way, one station would transmit a special FSK signal which the other station would receive. This FSK signal serves to alert the other station to start hopping as soon as the FSK signal stops. The FSK signal was generated by using the Send Sync switch on the rig. To set up the second station to use this FSK sync signal, there was a FAM (frequency-agile mode) switch position to enable the second station to lock onto the FSK signal.

When the FSK signal stopped, both rigs were in the hopping mode. The speed at which the hopping took place was 5 hops/s, which is slow, as hopping goes, but has many interesting features. The mode of transmission was SSB, and Dick's signal came in very well. I was surprised that the rig's synthesizer was right on each hop, which meant that the SSB signal was very clear. No "duck talk" was present, such as comes from being a little off with an SSB signal.

One of the main advantages of spread spectrum was the so-called antijam or interference-avoidance feature which happens because the background QRM is being changed every hop. We were hopping at 5 hops/s with this rig, and I was able to observe this effect. Dick's voice was more readable than when in the (non-hop) conventional SSB mode. We made a few experiments by moving the hopping sequence up a little to see what it would do against solid, congested SSB.

In the first part of the experiment, we were in the 80-75-meter band, which resulted in the hopping sequence varying mostly in the CW portion, but it would visit phone stations now and then. What did this sound like? Well, all the sounds that hams are used to were present, but every one-fifth of a second the sound would change! What you would hear was a snatch of RTTY, a small burst of CW, a few sounds from some SSB stations, and some snap of QRN, each lasting only a fifth of a second.

It was easy to hear Dick's voice with this ever-changing background noise because Dick's signal was strong. There was some fading now and then, and this let us see what a weaker signal would sound like. When K2SZE's signal became weak, it was still readable even when it started to fade into the strange background sounds. My old CW training came back to me, and I mentally started to try to shut out the background, just as you do when receiving a weak CW station in heavy QRM. But this time the background sounds were changing!

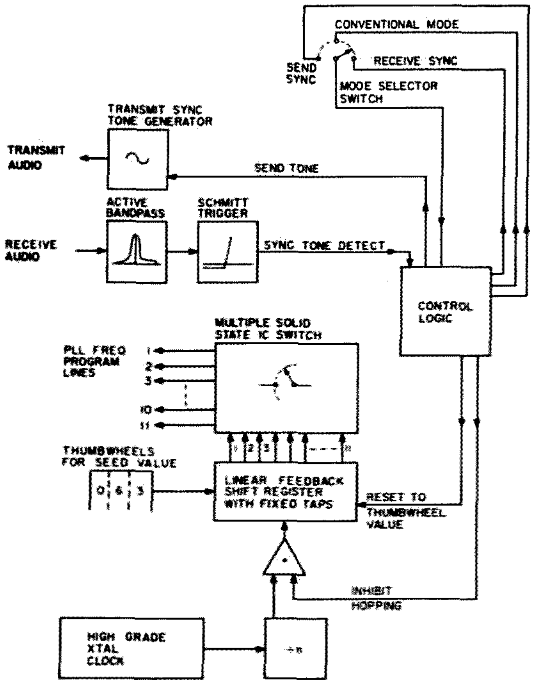

Fig. 2. Frequency-hopper controller board basic functions.

I would say that there was about 30% SSB sounds in the mix with the remainder being CW and RTTY. There was an advantage over normal SSB with this mix. Then we moved the hopping sequence into the 75-meter phone band. Both stations had to reset the service frequency higher and then go through the sync process again, which is not hard. This time, we had a mix of 80% SSB and 20% CW and RTTY. With this mix, Dick's signal was hard to hear. Because there was such a high percentage of SSB in the background, it was difficult to pick out Dick's signal from the rest. We tried to lock onto Dick's voice and ignore the rest. But this was difficult. Things were much better with more CW and RTTY in the mix and downright hard with a high percentage of SSB.

What conclusion can be drawn from this? With slow hopping (5 hops/s), SSB frequency-hopping does well against CW-like signals and poorly against voice-type signals. The fact that we were hopping at 5 hops/s didn't allow us to take advantage of a property that fast hopping has. If we were hopping faster (say 25 times a second), very short snatches of the background noise would be received. As the frequency is changing so fast, the sound of each of these snatches would just meld together and form a kind of buzz. The SSB voice signal would still sound like an SSB voice signal, but the background would sound very constant. With the right filters to treat the background buzz, the voice signal should be readable. This would happen even with a strong mix of SSB signals in the background because the amount of signal from each frequency would be very small. This is what we would like to try a little later with Experiment #2, which will allow us to build our own frequency-hopper rig out of old CB sets.

As part of the experiment, Paul turned on his Icom IC-701 so that we could hear with the other rig transmitting in the frequency-hopping mode.

Control Lines:	Function
1) SEND TONE	Turn on sync tone oscillator.
2) SYNC TONE DETECT	Presence of sync tone in receiver audio. Means that other unit has transmitted sync tone.
3) RESET SHIFT REGISTER	Clear out current contents of shift register and load value of thumbwheels.
4) INHIBIT HOPPING	Gate off the clock which drives the shift register.
5) MODE SELECTOR	Signal the mode we want to be in. There are three auxiliary lines associated with this line which are not named.
6) TRANSMIT ON	Key the unit's transmitter.

Sequence Logic
(Controlled by mode switch)
SEND SYNC

1) If hopping enabled, force to CONVENTIONAL MODE.
2) Lock out SYNC TONE DETECT.
3) Enable TRANSMIT ON. (turn on transmitter)
4) Enable SEND SYNC. (transmit sync tone)
5) Wait 3 seconds. (by an internal timer)
6) Disable TRANSMIT ON, SEND SYNC.
7) Disable INHIBIT HOPPING. (start hopping)

RECEIVE SYNC

1) If hopping enabled, force to CONVENTIONAL MODE.
2) Enable SYNC TONE DETECT.
3) Wait for SYNC TONE DETECT to go high. (sync tone received)
4) Wait for SYNC TONE DETECT to fall. (sync tone falls)
5) Disable INHIBIT HOPPING. (start hopping)
6) Lock out SYNC TONE DETECT.

CONVENTIONAL MODE

1) Enable INHIBIT HOPPING. (stop hopping)
2) Trigger RESET SHIFTREGISTER. (load thumbwheel values)
3) Lock out SYNC TONE DETECT. (in case we are resetting)
4) Disable SEND SYNC, TRANSMIT ON. (in case we are resetting)

Note: Conventional mode also is a recovery position which is used by the other two modes and by the operator to recover from a foul up such as no sync tone being received for a very long time when one is expected.

Table 1. Functional frequency-hopper control board logic sequence.

Paul picked out a place on 80 meters where it was quiet and let the receiver stay there. We didn't hear K2SZE's signal on this receiver, partially because it wasn't connected to an antenna. When we went to the transmit mode, every once in a while you would hear a snatch of sound like "aup" or "thu," but it would be gone as quickly as it came. This was the result of the rig's hopping in a random way.

Experiment #2—Proposed

A few of the AMRAD Spread-Spectrum Special Interest Group have been interested in doing something with old CB transceivers. Allan Kaplan W1AEL in Richardson, Texas, has a bunch of good ideas. His group was in active search of a number of Hy-Gain surplus CB boards to use as the basis of a 10-meter frequency hopper.

I was able to get hold of two SSB CB transceivers which were modified for 200 channels and had seen extensive use in another "service." These rigs have almost identical internals and use the standard μPD858C synthesizer chip. This chip has a number of components for a synthesizer built right onto the chip. External to the chip is an active bandpass filter, a main vco chip (which produces the output frequency), and a number of mixers and oscillators used to mix the vco output for use in the CB transmitter and receiver.

In order to frequency hop, there are three things that need to be done: 1) Change the mixer crystals so that the rig operates in the 10-meter band (this is in progress now); 2) Modify the feedback filter so that the synthesizer will lock up faster; 3) Hook the BCD frequency programming lines to a controller board.

The controller board (Fig. 2 and Table 1) will have a linear feedback shift register which has parallel output and will gate an IC which has 8 SPST switches implemented in solid state. This IC will do the actual switching of the synthesizer programming lines for isolation's sake.

A second stage of the board will be used to sense/send a tone which will be used the same way that the special FSK signal is used by the commercial rig mentioned above. When the signal appears, the clocking associated with the shift register will go into a make-ready-to-hop state. Then, when the signal ends, hopping will start and continue until the Stop Hopping switch is pressed. Lastly, a timing source is needed, and this will be supplied by a high-stability crystal oscillator which will be on board as well.

K2SZE points out that timing is critical with fast frequency hopping. For now, we don't plan to hop very fast. Only when we have gained more experience with slow hopping will we try the faster stuff.

One problem being researched is that of how to get the loop filters of the synthesizer to react faster. The loop filter sits between the output of the phase comparator/charge pump and the vco. Its job is to filter the correction voltage to the vco to eliminate high-frequency components. So, the output of the phase comparator/charge pump goes through a low-pass filter before being applied to the vco.

This loop filter in the two CB rigs consists of an active filter which is part of the μPD858C and a second filter which is a bandpass filter implemented as an active discrete transistor amplifier. The feedback network for the active filter within the μPD858C is via a resistor-capacitor combination attached to some of the 858's pins.

Both CB rigs are slated to be modified in the same way so that there will be two rigs which do the same thing right off. Differences in the synthesizer design or the controller board will probably produce a different hopping sequence. So, if you plan to do this *always* get at least two rigs of the same kind. Fig. 2 and Table 1 give more details.

For the Record

Since we started this project, we've learned a lot about the spread-spectrum mode which was heretofore unknown in the amateur community.

The FCC has certainly been forward looking with regard to spread spectrum as well as other advanced amateur technology.

At one point we talked about the idea of kits being made available for the builder. It turns out that we have a lot more ground to cover with the experimental aspects of spread spectrum before we can get to a prototype. The whole idea of the STA is to experiment. So, if you're not sure how to proceed and want to talk it over with someone, I suggest that you find someone close to you and work together. The converted-CB approach seems the simplest way to start. ■

A Visit with SVØAY

—the road to paradise

"The difference between the permanent residents here and the tourists is that the islanders wear clothes!"

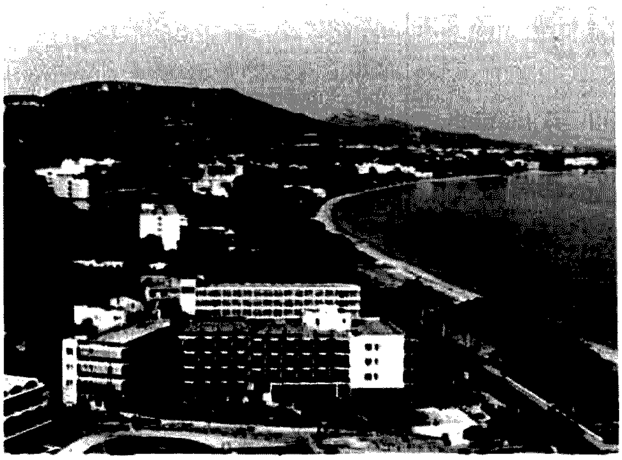
So says Joe Nearns SVØAY at his QTH on the western coastal road, only a short distance from a beach on the Greek island of Rhodes in the eastern Mediterranean. The island is so far east that the mountains of Turkey can be seen to the north only twenty miles away.

The principal business on Rhodes is tourism, and vacationers arrive daily from all over Europe to enjoy the delightful beaches and warm water, and to get a maximum tan in the hot sun. It is especially interesting to explore this island, with its over 3000 years of mainstream history.

The island of Rhodes was centrally located for the ancient Greek trading routes to the Middle East. The Apostle Paul is said to have taught there, and during the time of the Crusades, the island was governed by the knights for over two hundred years. Much remains of the fortifications of that era, including a wall around the ancient city which is still largely intact.

At the village of Lindos, on the eastern shore, the remains of a Greek acropolis can be explored, including the changes made during the middle ages. The "Colossus of Rhodes," one of the seven wonders of the ancient world, actually was the lighthouse marking the entrance to Rhodes harbor. The harbor is still very much in use today, guarding a mixture of picturesque Greek fishing boats, private yachts, commercial shipping, and pleasure-cruise vessels. In fact, one of the ways to visit Rhodes is to take a Greek Island cruise out of Athens.

Joe has a location almost ideal for ham radio, a good, unique callsign, almost no local competition (there are only two other hams on Rhodes), and a nice flat roof on his house for antenna tuning! It did, however, take him eight or nine months to get his call, after applying for it. He maintains daily schedules on 40 meters with a number of hams in the Greek islands as well as weekly schedules



The western beach area of Rhodes. Joe's QTH is just around the arm of the bay in the upper right, along the coast road.

Joe Nearns SVØAY at the rig in his shack at home in Rhodes.

A view of the harbor showing commercial and pleasure boats and some of the ancient fortifications.

George N1BEP sitting on the wall of the ancient acropolis at Lindos, southeast Rhodes. The small bay below the cliff is a tiny port for fishing and pleasure boats. The climbing scenes from the movie "The Guns of Navarone," starring Anthony Quinn, were filmed on the cliffs below the acropolis.

with Argentina and the Philippines.

Although Joe has lived in several other countries and has had LU and EL2EA calls, he still retains his US call, W5NTS. Joe doesn't go after DX on a regular basis—no contests or DXCC—and sometimes he says that he has to fight off the pileups that occur when conditions are good.

QRM is very bad on 40 meters from the broadcast stations, and during dry periods QRN is bad from the corona discharge on the local power lines, apparently due to salt deposits on the insulators—one liability of living near the beach.

The language is difficult to learn since it is hard to read the Greek alphabet. There is no English-speaking community on Rhodes. Therefore, Joe's two older children (boys) attend boarding school in Athens, and the younger girls study by correspondence course.

In their spare time, the whole family goes camping around in the many beautiful spots on Rhodes, especially after the tourists have left. ■

Reviewing Daiwa's New Meters

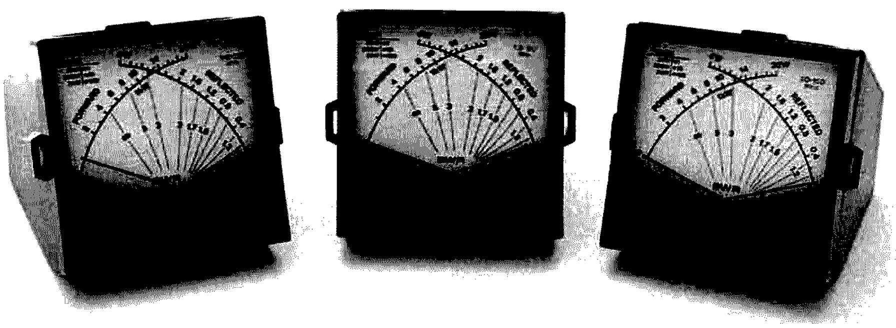
—fiddle-free swr measurement

Much as I hate to admit it, I am always in search of the ultimate swr meter. I am well aware that the subject of swr is a controversial one. In fact, swr is high on my list of discussion topics to avoid at all costs, right up there with the relative merits of quads vs. yagis, the number of angels that can dance on the head of a pin, and the ARRL. Particularly if the conversion is taking place on 80-meter phone!

After sober consideration and a mild sedative, most hams will agree that there are merits to having an swr meter in the antenna line at all times. I can't be the only one who has neglected to flip the antenna switch when changing bands or forgotten to tweak up an antenna tuner when moving from the phone portion of the band to CW. In these and similar situations, a well-designed swr meter in a prominent location can save the day, as well as a set of transmitter finals.

For this type of continuous monitoring, the last thing you need is the latest laboratory-standard instrument, complete with felt-lined wooden case and a calibration guarantee signed by the Almighty. Spend the money on intoxicating women and loose beverages instead. What you want is a simple meter that displays swr without requiring you to flip any switches or tweak any knobs. With very few exceptions, wattmeters are all pretty much alike. They differ primarily in the level of accuracy they provide, and almost all require you to flip switches and tweak knobs. Some of the most intriguing flipless, tweakless wattmeters can be found in the Daiwa line of radio accessories.

At first glance, these meters look somewhat imposing, with a pair of meter needles and a series of red lines marked on the front panel. First impressions aren't always right! Anybody can learn to read a cross-needle meter in less than a minute, and once you've learned how, you'll be hooked forever. The scale on the left side of the meter face reads forward power, and the scale on the right side reads reflected. These are the scales you would pay attention to if you are interested in measuring absolute values. Want to know swr? The point where the two needles cross displays standing wave ratio. No switches to flip or knobs to tweak! These meters may not replace the venerable Bird for test-bench applications requiring extremely high resolution and accuracy, but they are exactly what most hams need to monitor station performance on a day-to-day basis.



Swr meters from Daiwa.

Ham Shack Design for Beginners

—Novices, take note!

One set of questions usually asked by new hams concerns the practical aspects of setting up a new station. These questions are often difficult to answer since they can affect the new ham's entire family, assuming the station is to be located at home.

Question: I just got my call in the mail and now want to set up my station. What is the minimum I need for the operating position?
Answer: I have seen ham shacks ranging from a separate building containing a TV set, stereo, bathroom, and refrigerator to one built into a single desk drawer. However, at a minimum you need an ac line outlet, a ground wire, and a way to run your antenna feedline.

Q. Let's take these one at a time. What about the ac line?
A. It would be nice if you had a single 120-volt line direct from your house fuse box with 20-Amp service and a second 240-volt line for a linear amplifier. However, most of us end up plugging in a distribution box containing four or eight outlets, a fuse or breaker, a switch, and a pilot light. If you want to use a commercial box, there are several available, but they are only fused on one side; you really want fuses on both sides. See Fig. 1.

Q. Why fuse both sides? I thought that most 120-volt ac lines have a neutral or common which is grounded.
A. It is a matter of safety. If you get a lightning strike that enters your home wiring, it is nice to have both sides of the line fused so that there is a chance the fuses or breakers will blow and protect your equipment.

Q. I take it that when I want to operate the station I simply have to flip one switch and I now have power to all the equipment?
A. Yes, but you will also want to have one or two ac sockets which bypass the switch so that power is always available to your clock, desk lamp, or any other equipment which you might want to use independent of your rig. You also might consider using a key switch if you have any small children around so that they cannot turn on your station.

Q. How much power should I plan on?
A. As a rough approximation, complete a table for your station such as the one shown in Fig. 2.

Q. Well, just how many outlets do I want in total?
A. No ham in history has ever had enough outlets or current available. It is getting a little better now since many hams are also wiring

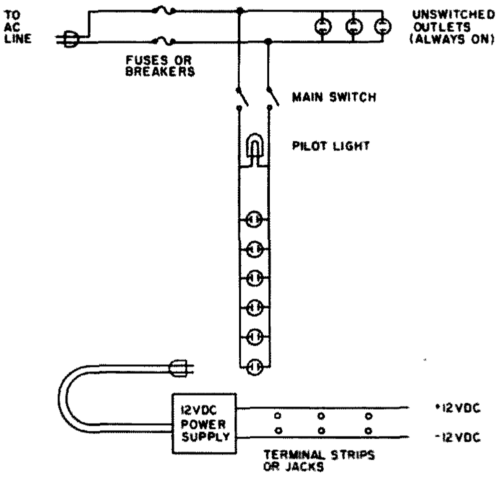

Fig. 1.

	Example (Watts)	Your Station
Rig	400	
Keyer	20	
Clock	10	
Outboard Active CW Filter	10	
Antenna Rotor	75	
Desk Lamp	100	
Total	615 Watts	

Example: 615/120 = 5.125 Amps 5.125/0.8 = 6.4 Amps total
Your Station:_____/120 = _____Amps
_____/0.8 = _____Amps total
Take the total power and divide by 120 to get the current, and then divide by 0.8 to account for any power factor. The number you get is the Ampere load you will have to supply from the ac line.

Fig. 2.

their shacks with both 12 and 5 volts dc.

Q. Why would I want to do that?
A. Typically, you will end up with a main rig and then a half dozen solid-state accessories. If you build them independently, there also will be a half dozen small dc supplies, each of which must be plugged into the ac line. If you plan ahead a little and set up a 12-volt power supply at a few Amps, you can power all of these units from the one supply. Most of the circuits around these days use 12 volts dc, with the exception of those using 5-volt digital logic. You can add a separate 5-volt dc supply or include a dropping resistor and voltage regulator in each of the 5-volt units.

Q. Will I be safer if I connect the ground bus to the ac power system?

A. Unless you are an experienced electrician, the only grounds you should use with the ac line are those built into the three-wire cords common on some equipment. Keep your ground bus separate.

Q. Since the ground bus is not connected to the ac line, what do I need it for?

A. You need a good ground primarily for safety. I use a 1" × 1/2" aluminum bar, running the length of my operating table. Every 6" I have drilled and tapped it to connect braid from the bus to each of the pieces of equipment. When I put a piece of equipment down on the operating table, I connect it to the ground bus before I plug it in, and when I want to remove it, I unplug before I disconnect the ground. If anything goes wrong, at least I don't end up with the 120-volt line voltage on the front panel of the equipment. See Fig. 3.

Q. Where is the ground bus connected to? Can I use a hot-water pipe rather than a cold-water pipe? How about the radiators? How about the this or the that?

A. Yes, yes, yes. If in doubt, connect it to all of them. No one has an ideal ground and you cannot hurt anything by connecting it to more than one ground. Just stay away from the ac wiring. The most important thing is to use wide braid or heavy aluminum wire, securely clamped. You should also remember that these mechanical (non-soldered) connections corrode and should be cleaned and tightened periodically.

Q. Is this ground bus the same ground that is shown in the pictures of antennas?

A. If you are using a coax-fed antenna, such as a dipole or beam, the shield of the coax will be connected through your rig or matchbox to the ground bus. But the bus plays little if any part in the antenna performance. However, if you are using a matchbox to feed a long wire with no radials, the ground bus provides the other end of the antenna circuit and is doubly important. See Fig. 4.

Q. What about antennas in setting up my shack?

A. Your shack must be located in such a way that you can run your antenna feedlines to the operating position. For this reason it is always nice to be close to an outside wall. Remember that no ham in history has ever had enough antennas, either. Plan ahead, and if you expect to run three lengths of coax into the shack, *plan* for at least six or eight and make whatever opening you drill through the wall big enough for the additional feedlines. It is much easier to stuff the extra space with loose fiberglass insulation than to go back and drill some more. Fig. 5 shows one possibility.

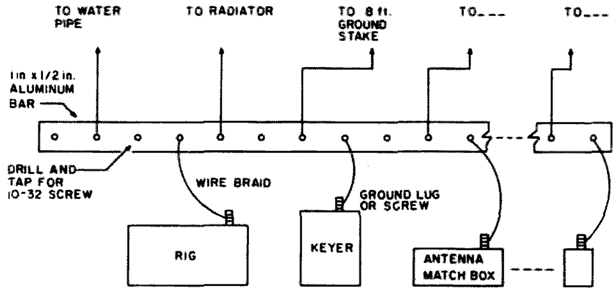

Fig. 3.

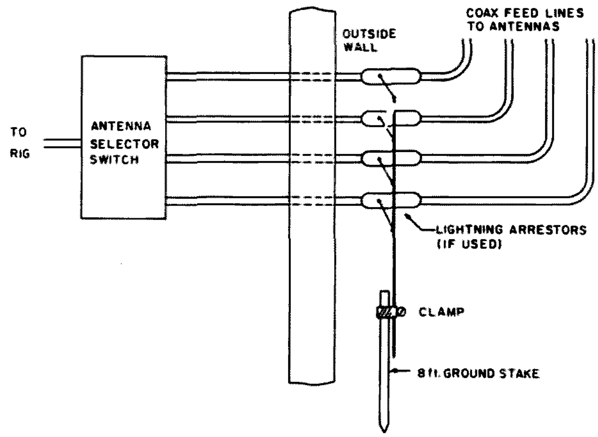

Fig. 4.

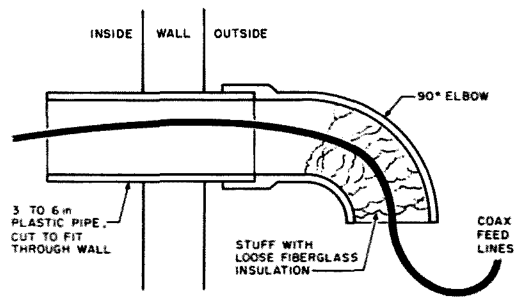

Fig. 5.

Q. I keep seeing pictures of ham shacks where the antenna coax, ac line, ground bus, and all of the wiring is hidden behind custom-made panels. Some of these shacks would put the best commercial installation to shame. Is this what I should plan on?
A. There is no question that designing and building a neat, custom-made installation provides some hams with just as much fun and challenge as working for DXCC. However, most hams "rack it and stack it" in the most convenient way. Whatever you do, remember that you will be making changes in your equipment, adding boxes and replacing boxes, so that you want the flexibility to change without major woodworking. If you do decide to "build it in," remember to leave room to get behind the units to work on the wiring.

Q. What about furniture?
A. My shack consisted of a folding cardtable for many years. I am now using an old desk with a spare door screwed on top to provide

more area (Fig. 6). Old desks are nice since they give you drawers for storing logs, callbooks, headphones, and several cubic feet of clutter which otherwise would lay around. You also can get more top area by mounting a shelf above the desktop with sections of 2″ × 4″ wood and L-brackets. Measure the height of the largest unit you expect to have on the bottom and then mount the shelf at least 4″ above this height to give heat a chance to escape.

Q. How about the little things, such as a chair, lights, and such?

A. Spend six or eight hours in a contest and you will find these are not such little things. Some phone operators literally use large armchairs as they claim "armchair copy." CW operators usually opt for a stiff-backed chair with a soft cushion. The cushion is optional until contest time. The key thing is to be comfortable for the periods you are operating. For this reason, you also will want to modify your rig to fit your needs.

Q. (with horror) Modify my brand new rig? Won't that reduce its value when I want to sell it?

A. These modifications won't. First, look at the knobs. On CW I tend to ride both the volume control and the tuning control. I found it much more comfortable to replace the 2″-diameter knob on my Heath SB-102 with a larger, 3″ knob, and the fluted volume control with an identical size non-fluted knob. You also can change the height of the knobs by either drilling holes in the desktop for the rubber feet (lower the rig) or by placing the rubber feet on small wooden blocks to raise the knobs. You also can tilt the rig (Fig. 7).

Q. Why tilt it?

A. Some people are more comfortable with the rig tilted backwards to put the frequency dial more fully in their line of sight. Others like to tilt it down. Since the total investment is a few pieces of wood, it pays to experiment. Also check that the room lights or your desk lamp don't reflect in or wash out the numbers on the new rigs with the digital dials.

Q. I already can see that I will run out of space quickly. Where else can I put things?

A. If you home-brew some of the station accessories, such as audio filters and keyers, you can mount them inside a 1″-high chassis and slip them under the rig. A second approach is to suspend them from the bottom of the shelf. Separate power supplies can be placed under the operating position on the floor, and you can always hide things such as antenna rotor controls in a drawer.

Q. You said that the shack location and arrangement could affect the entire family. How is that?

A. Late-night operations with a loudspeaker or most of the old RTTY units pose an obvious problem. If you set up in a remote corner of the basement, consider including an intercom so that you can be called for dinner. An extension telephone is almost a necessity, but be forewarned, it will ring just as it is your turn to call the A9 station on the DX net.

Q. Anything else?

A. There have been several million ham-years of experimentation with the arrangement of stations. The best bet is to visit a number of stations and see how they are arranged. Don't be over whelmed by the amount of equipment you see. What you are looking for is how do you sit and how do you reach things. Then experiment before you plug in a single wire. The only thing for certain is that you will change the arrangement before very long and end up with just the right arrangement to suit *you*. ■

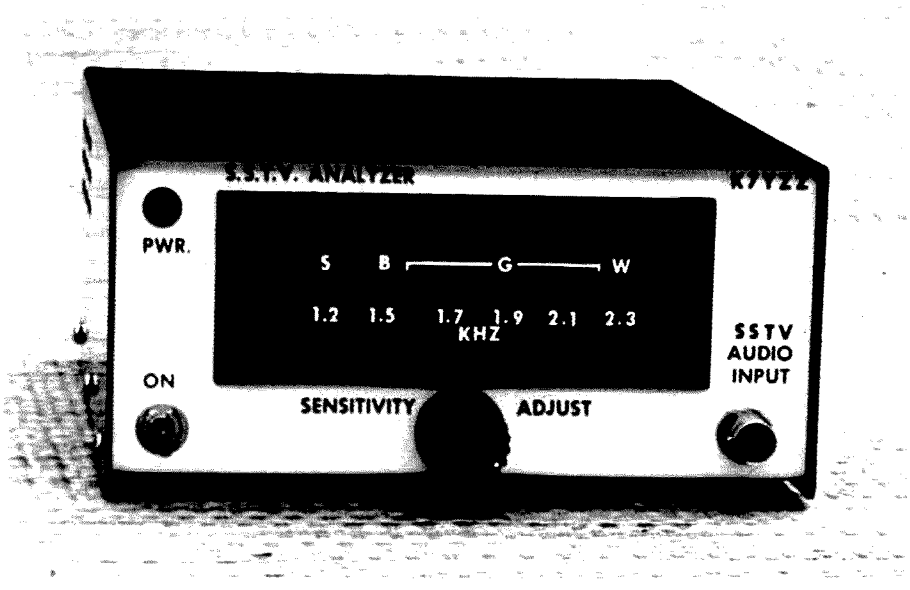
SSTV Signal Analyzer

—simple and inexpensive, even

For those of us who are experimenting with slow-scan TV, it becomes very apparent that one item required in the ham shack is a device that will indicate to the SSTV operator that the received or transmitted SSTV signal is properly adjusted for optimum gray scale. Audio frequency spectrum analyzers designed for displaying the SSTV audio signal on a small CRT have been described in previous articles.[1,2] These analyzers required the construction of high-voltage supplies to power the CRT and associated deflection circuits. Components of this type are becoming more and more difficult for the builder to locate.

A spectrum analyzer utilizing solid-state design was described recently that covered the audio range of 30 Hz to 16 kHz and was far too sophisticated for SSTV application.[3] Another pair of devices that appeared on the market were investigated for application in an SSTV signal-analyzer function. They were the LM331 frequency-to-voltage converter[4,5] and the LM3914 dot/bar display driver.[6] Several different circuit configurations were built in an attempt to use them as an SSTV audio signal analyzer. The initial results were very disappointing. The circuits were subject to input level sensitivity problems which adversely affected the display readings. The spectrum coverage also was determined to be unsuitable for SSTV application. However, from the results of the literature searched and with problems identified from the breadboard circuit experiments corrected, the configuration of a workable low-cost SSTV audio signal analyzer was developed.

The unit described in this article is of simple design and may be assembled from readily available components. It will provide the ham radio operator with information on the status of audio frequencies necessary for the proper transmission and reception of SSTV pictures.



The completed SSTV audio signal analyzer.

Circuit Description

The SSTV signal analyzer consists of five major items, an input signal amplitude limiter, an adjustable-gain operational amplifier, selective bandpass active filters, LED signal indicators, and a power supply (Figs. 1 and 2).

The incoming SSTV audio signal derived from the station's receiver or SSTV

picture-generating equipment is limited in amplitude by the limiter and is fed to an adjustable gain operational amplifier whose output is connected to six different audio bandpass active filters. The selection of component values for each audio frequency filter was made by a computer program for active filter design run on my microcomputer (Table 1). The SSTV audio frequencies selected were 1200 Hz (sync), 1500 Hz (black), 1700 Hz (gray), 1900 Hz (gray), 2100 Hz (gray), and 2300 Hz (white).

The audio signal appearing in the output of each active filter is fed to a transistor driving an LED indicator. When the appropriate SSTV audio frequency appears within the bandpass of the active filters, the resulting output causes the selected LED to illuminate.

Construction

The analyzer circuit was assembled on a perfboard pre-trimmed to fit the inside of a 6″ × 2¾″ × 7½″ cabinet. The perfboard is 4½″ × 4½″ (Radio Shack 276-1394) and is mounted on two ½″-high threaded metal standoffs. The IC sockets and component parts are point-to-point hand-wired on the back side of the board. This circuit has not been converted to a PC board. The bridge rectifier diodes and filter capacitors are assembled on a separate 2¼″ × 2″ perfboard which is mounted in the cabinet on ½″-high threaded metal standoffs.

The three-terminal voltage regulators are mounted on the back of the chassis which provides a ready-made heat sink. The total maximum current drain when all LEDs are illuminated is 82 mA, which is so low that the voltage regulators have a very small heat rise. The negative voltage regulator requires the use of insulating mounting hardware (RS 276-1371) for proper operation.

A piece of perfboard (4½″ × ¾″) was used to mount the six LED frequency display indicators. A strip of black plastic electrical tape was attached to the surface of the display board on the side facing the front of the cabinet to improve display contrast. A bezel with a high-contrast filter for LED displays (RS 270-301) was mounted on the front panel. Decals were applied to the optical filter to identify the SSTV audio frequencies being detected and displayed. The six LEDs were cemented in place on the display board using model airplane cement. The display board was mounted behind the bezel using the bezel's mounting studs and small 1/8″ fiber spacers.

Test and Adjustment

The power supply is the first part of the unit to be tested. Power is applied to the transformer and the regulator outputs are checked for the proper plus and minus 15 volts. The power supply is then connected to the circuit board and pin 4 of each LM324 is tested for plus 15 volts and pin 11 for minus 15 volts.

An audio signal generator[7,8] is connected to the input and the frequency of

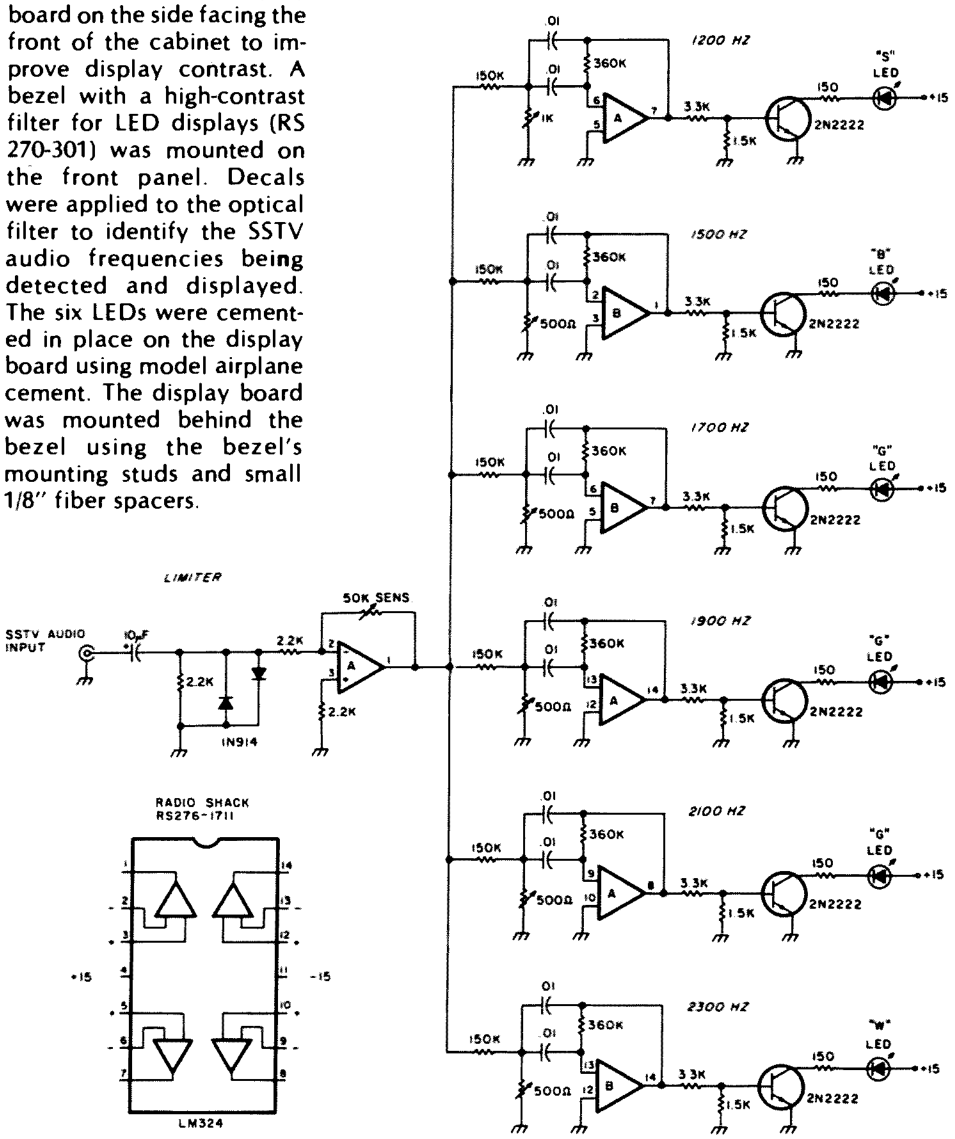


Fig. 1. SSTV audio signal analyzer.

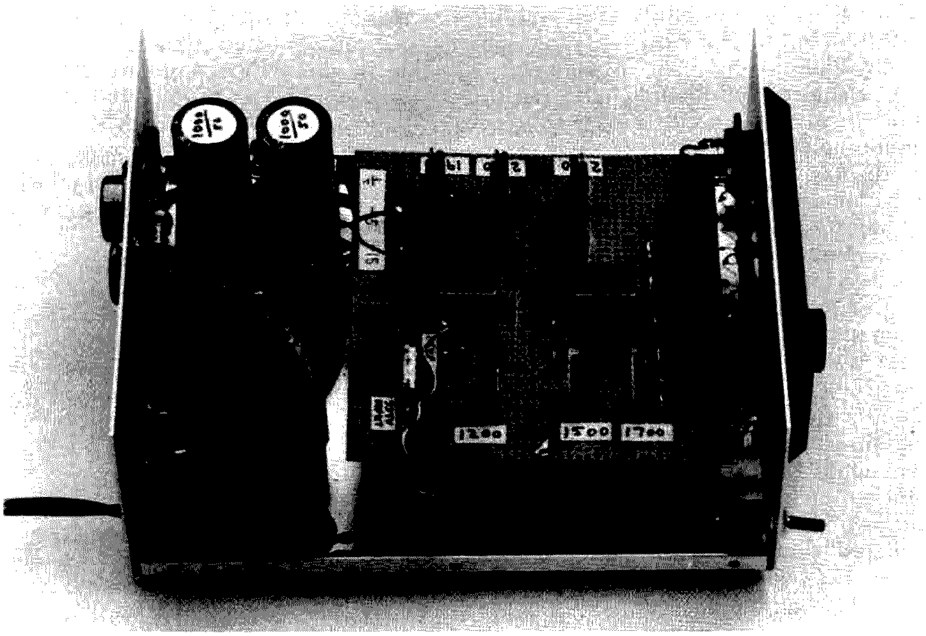
Desired Frequency (Hz)	Computed Frequency (Hz)	−3dB Bandwidth (Hz)	Gain	R1	R2	R3	C1 = C2 (uF)
1200	1200	88.4	1.2	150k	490	360k	.01
1500	1508	88.4	1.2	150k	310	360k	.01
1700	1713	88.4	1.2	150k	240	360k	.01
1900	1900	88.4	1.2	150k	195	360k	.01
2100	2098	88.4	1.2	150k	160	360k	.01
2300	2327	88.4	1.2	150k	130	360k	.01

Table 1. Computer-derived data for SSTV audio signal analyzer bandpass active filters.



Internal layout showing components mounted on perfboard on metal standoffs.

1200 Hz is selected. The trimmer control on the 1200-Hz audio filter is adjusted for maximum brightness from the 1200-Hz LED frequency indicator on the display. The signal generator is now switched to 1500 Hz and the appropriate audio filter trimmer control is adjusted for maximum brightness from the 1500-Hz LED on the display. The same procedure is to be repeated for the remaining four frequencies. (See Fig. 3.)

An audio signal generator is again reset to 1200 Hz and the sensitivity setting is reduced until the 1200-Hz display LED just illuminates. The trimmer control on the 1200-Hz active filter is again adjusted for maximum brightness on the 1200-Hz LED indicator at this reduced input sensitivity. This procedure is then repeated for the remaining five frequencies. The last test is to manually step the audio signal generator through the six frequencies and observe that each LED turns on individually as the signal generator is switched from 1200 Hz to 2300 Hz. The SSTV audio signal analyzer is now ready for use.

Operation

Connect the SSTV audio signal analyzer to the audio output from a receiver that is tuned to an SSTV signal, the output from an active SSTV camera system, or an SSTV tape. Advance the sensitivity control until the LEDs are flickering from the presence of the SSTV audio signal. When the receiver is properly tuned to an SSTV signal, the 1200-Hz sync frequency indicator will flicker at a steady rate of 15 Hz.

The 1500-Hz to 2300-Hz frequency indicators will be illuminated depending upon the picture video content. Fig. 4 shows how the analyzer display will present different SSTV signals. If the sensitivity control is set too high, all LEDs will be driven on.

Conclusions

This little unit should be of considerable help in enabling the SSTV experimenter to send pictures of improved quality and to act as an aid in receiving pictures.

I would like to hear from those who build this unit as to how it performed for them. Questions regarding the unit are welcome but please enclose an SASE. ■

More for Less

—this tune-up procedure gives more RTTY output, less heat to dissipate

Using an SSB rig for RTTY can be hard on tubes, depending on how you tune up your rig. Many hams, I have found, tune their rigs the same as they would for CW or SSB, then reduce the drive to about half power or half the plate current. This is a poor method to use as you are operating on a very low part of the efficiency curve (power input versus power output) of your final tubes. Try the above method into a dummy load, reducing your drive after tuning for CW to half the plate current and note the power on a power meter. Now, figure your input power (Ep × Ip) and subtract the output power from the input power. The result is the amount of power (heat) your final tubes must dissipate.

Now retune, using the same amount of drive you used when tuning up for CW, but instead of loading for maximum output power, reduce your loading to about ten mils over one-half the plate current you were loaded to for CW, retuning the plate for a dip as you reload. Now, for RTTY operation, adjust the drive to the point where your plate current (half the CW current) just begins to drop. This value should be one-half the current you normally load to for CW. Your plate input power should be the same now as before, but check the output power meter reading and you will find about twice the power output as before. And, again, subtract the output power from the input power, and you will find your tubes now have less than half the power (heat) to dissipate as before. Adding a muffin fan to draw the warm air out of the final compartment will be an even greater tube saver.

If you're using a linear, it should be tuned after your exciter and should be tuned for maximum output with the available drive you now have from your exciter tuned for RTTY. If you wish to run less than the maximum your linear will put out, reduce the loading on the linear, retuning the plate for the desired power output. Do not reduce power by reducing the drive on the exciter as this puts your tubes in the low efficiency part of the power curve.

Don't take my word for this method—try it! Your tubes will love it. Test this method and prove to yourself it works, and save on those tubes.■

Inside the Palomar Preamp

—big ears for your receiver

Regardless of the sophistication, cost, or complexity of one's amateur radio equipment, there always seems to be room for adding a few custom accessories to round out the station's inventory. One of the most common accessories is the receiving preamplifier. Most of the best-designed (and costly) transceivers and receivers sold today have enough sensitivity and front-end rf selectivity to make the purchase of a preamplifier of questionable usefulness—though this "armchair speculation" does not always hold water. Older and especially vacuum-tube era and SWL-oriented equipment can almost always profit from the installation of a preamp. Thus I looked forward with anticipation to trying out one of the new Palomar Engineers P-310X transceiver preamps. I obtained one at the 1981 ARRL National Convention at Orlando, to try out with some 1980s vintage gear.

The new Palomar unit is the successor to an earlier model, introduced about three years ago, that was styled along the lines of most Palomar accessories: die-cast aluminum cabinet with a bright red-orange cover. The older unit covered the 1.8-54-MHz range and featured circuitry and gain comparable to the newer version, but it had a transmit-receive (T/R) relay that occasionally gave trouble. The new bi-linear P-310X is actually one of a line of four similar preamps offered by Palomar. Its closest cousin is the P-312X, which is similar but is designed for 12-V dc operation. The P-308 is a receiver-only ac-powered preamp, while the P-305 is the same receiver-only unit but intended for 9-V dc operation using a standard transistor radio battery. Though all models are similar, the P-310X is the top of the line; its bi-linear circuitry features T/R sensing for automatic cutout of the preamp while transmitting and the built-in power supply allows convenient hookup to an ac outlet by means of the six-foot three-conductor power cord.

The preamp uses a tuned rf amplifier which covers all of the ham bands from 160 through 6 meters (1.8 to 54 MHz) and all radio services in between. The continuous coverage feature also makes it suitable for general-coverage and SWL purposes. At the heart of the unit is a low noise dual-gate FET transistor amp which affords a 1.5- to 3.5-dB noise figure. Input and output im-

Four New Books for the Experimenter

Imagine that it is a rainy Saturday afternoon. Sol has gone on a rampage, leaving your favorite DX band in disarray. Instead of searching for a new country to work, you decide to warm up the soldering iron and build a simple yet useful project. Next you turn to the bookshelf to find a source for your rainy day fun.

Beginner's Handbook Of IC Projects

The lucky experimenter will find a copy of the *Beginner's Handbook of IC Projects* by David Heiserman. This 216-page Prentice-Hall publication covers building, troubleshooting, understanding, and testing elementary integrated circuit projects. The emphasis is on construction. Each of the 84 projects has a schematic diagram accompanied by a parts list and brief description of circuit operation. The author encourages the builder to use a solderless breadboard to debug and experiment with the circuits; they can later be built in a more permanent fashion.

The circuits in the *Beginner's Handbook of IC Projects* range from a "Simple Light Flasher" to a "15-Channel Rf Synthesizer." The parts required to build the projects include garden variety TTL chips as well as more exotic linear ICs. If your junk box is not up to snuff, then you can get most of the components from Radio Shack or one of the mail-order houses. Detailed pinout and function information for the ICs is given in an appendix.

The projects in this handbook are not earth-shattering achievements that will change your life, but they are certainly fun and educational. If you are a hands-on type who enjoys simple yet state-of-the-art projects, then consider adding *Beginner's Handbook of IC Projects* to your library. Both hardbound and paperback editions are available from Prentice-Hall, Englewood Cliffs NJ 07632.

Ed Noll's Solid State Circuit Files, Volumes I and II

Have you ever wondered just what a common collector amplifier does or how a counter circuit works? Your search for this kind of information might lead you to *Ed Noll's Solid State Circuit Files*. This two-volume set is published by Howard W. Sams and Company. Each book is designed to give electronics buffs practical experience with the circuits that form the building blocks for our modern-day technological wonders.

Volume I of *Solid State Circuit Files* covers bipolar transistor, FET, and linear IC circuits. There are more than 60 circuits, starting with simple transistor amplifiers and progressing to the popular linear IC devices. Each file includes a circuit diagram, a detailed technical description, and a suggested procedure for experimentation. Digital circuits are featured in Volume II. The 61 files are evenly split between CMOS and TTL applications that range from basic gate functions to multichip counter-display designs.

The student or serious experimenter who is armed with *Solid State Circuit Files*, a breadboard, and a handful of parts can obtain a good understanding of what makes a circuit tick. If you have already mastered the basics, then the circuit files can be a helpful reference when you want to refresh your knowledge of a specific circuit: Volumes I and II of *Ed Noll's Solid State Circuit Files* are available from Howard W. Sams and Co., 4300 West 62nd St., PO Box 7092, Indianapolis IN 46206.

Troubleshooting Solid-State Circuits

The third book that you might reach for on a rainy afternoon would be *Troubleshooting Solid-State Circuits* by George Loveday and Arthur Seidman. The core of the text centers on a "concise description of major solid-state devices and their operation in practical circuits . . . followed by a discussion of how these devices and circuits fail and what troubleshooting techniques are employed to isolate and correct the fault in minimum time."

Troubleshooting Solid-State Circuits is written as a study text for a course in electronics troubleshooting. There are exercises for the student to solve and answers to the exercises in the back of the book. This is *not* a how-to-do-it style book. You won't find step-by-step instructions to build a super-duper bang box; instead, you will have a resource for learning how basic circuits operate and how to diagnose their ills.

The first chapter can be particularly helpful to a beginning troubleshooter, since it describes how to use measuring instruments as well as the basic procedures used to diagnose even the most complex electronic equipment. A 106-page softbound edition of *Troubleshooting Solid-State Circuits* is available from John Wiley & Sons, 1 Wiley Dr., Somerset NJ 08873.■

CB to 10
—part XXXI: simplified offsets

With the growing number of CB-to-10-conversion articles, an urge to do my part and liberate one from 11 meters finally got the best of me. I obtained a Realistic TRC-452 and was then faced with the problem of which of the many band plans to use. A listen on 10 with the FT-101 only served to compound the problem. Then along came the January, 1980, *73* with a CB-to-10 FM conversion, and I was sold!

A Sams for the 452 was obtained and studied at great length. The TRC-452 uses a uDP-585 chip as the heart of the synthesizer. This chip has a BCD programmable divider, so it was decided to use thumbwheel switches for channel selection.

The unit was then placed on 10 FM using the January, 1980, and November, 1978, *73*s as a guide. The coverage using the thumbwheel switches is 29.000 to 29.990 MHz, so care must be used to ensure that all transmissions are in the amateur bands, but no trouble has been experienced with this. If you are nervous, an additional circuit could be added to prevent out-of-band transmission, but that's another project.

The only thing left to do was to find a *simple* circuit to obtain the 100-kHz offset used by repeaters on 10. Another search through back issues of *73* yielded the 600-kHz offset for 2m which became the inspiration for the circuit in the accompanying diagram.

The offset circuit consists of two main portions: the subtraction logic and the switching logic. It is placed between the 100-kHz BCD switch and the programmable divider inputs. Four exclusive NOR gates are used to achieve subtraction in conjunction with two NAND gates used as inverters and four 1N914 diodes wired as OR gates. The 74LS266 was chosen, as were all of the parts used, because it is readily available. Since it uses open collector outputs, resistors R7 through R10 must be used, but if a 74135 exclusive NOR gate package can be located, the four collector resistors can be eliminated, further simplifying construction. Resistors R1 through R6 are all pulldown resistors to ensure that the gates see the correct logic levels.

The 74157 is a quad 2-line-to-1 data selector. A pair of 7400 NAND gates and a 7805 regulator to interface the offset circuit to the radio make up the switching logic. The TRC-452 uses an 8-volt line which goes low on transmit to switch the radio between receive and transmit. This line is brought down to the 5 volts required by the TTL logic by the 7805. A switch on the front panel is used to remove the 8-volt transmit line when no transmit offset is desired.

If you sit down and work out the innards of the subtraction logic, it will become obvious that it is a binary rather than a true BCD subtraction, but this is really only a problem using BCD switches when 1 is subtracted from zero. The answer is 15 instead of the 9 we would get with a BCD subtraction. Rather than add more circuitry to gloss this over, I decided to use a NAND gate left over to sense this invalid code and inhibit the offset. This is the function of U3C and conforms with the main design goal of a simple, easy-to-build circuit.

Hopefully, this 100-kHz offset will be of use to others who are converting this or similar CB units for use on 10-meter FM. Pick up your soldering iron and have at it! I'll see you on 10 FM.■

An X-Band Swept-Signal Source

—one for the road

Tuning up a waveguide filter for an X-band requirement can be a tedious job. A swept-frequency oscillator seemed to be in order. The sweep circuit must tune an oscillator across the band of interest. It should provide a voltage ramp which rises in amplitude, abruptly falls to zero, and then repeats itself. The width and amplitude must be adjustable in order to control sweeping in the band of interest. This same sweep voltage could be used to provide the horizontal sweep for an oscilloscope, and when a detected output is applied to the vertical amplifier of the oscilloscope, a visual pattern of the passband of the filter can be observed. This form of presentation also would be helpful when tuning up an X-band horn antenna, although a sensitive receiver would have to provide the vertical sign.

A sweep circuit was designed which was applied to the varactor tuning capacitor of a Gunn diode oscillator. It performed very well for both applications. A waveguide cavity wavemeter then was inserted in the detection waveguide to provide a discontinuity in the trace which could be moved as the cavity wavemeter was adjusted. This provided markers that would assist in indicating passband widths, and when the amplitude was calibrated, also indicated levels of attenuation or gain.

The filter being processed using the above technique is part of the front end of a radar detector which is centered on 10.525 GHz, the X-band police radar assignment. The filter forms a preselector for a varactor-tuned Gunn oscillator transceiver front end manufactured by Microwave Associates. The detected output of the transceiver is fed into a 30-MHz i-f amplifier. The combination makes an extremely sensitive radar detector.

The output of the superheterodyne receiver described above is directed into an alarm system which was tripping on signals from other services which were outside of the police radar band. The receiver also is used on the X-band amateur assignments. When the manual tuning control voltage is replaced with the output of the sweep circuit and the detected output and sweep voltages are applied to an oscilloscope, a panoramic view of the spectrum can be observed.

A second, swept Gunn

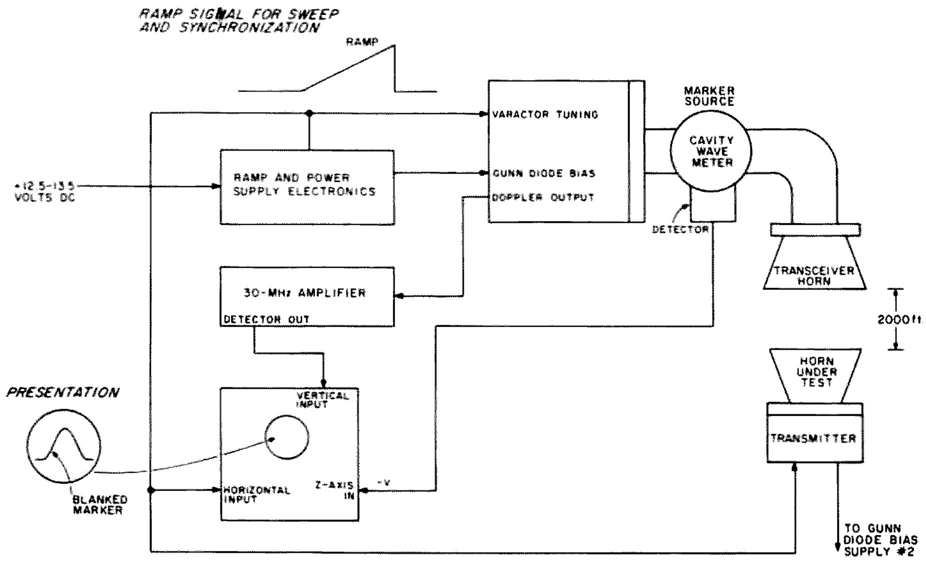

Fig. 1. Block diagram of method of presentation of swept signal.

oscillator is used in the manufacture and tune-up of horn antennas for radar detectors which I manufacture. The receiver described above is located at a considerable distance from the transmitting horn, and the sweep voltage from the transmitting oscillator is applied to the receiver varactor tuning over a long cable. This allows the receiver to be swept in synchronism with the transmitter and the resulting oscilloscope presentation used to assist in making adjustment to the horn antennas.

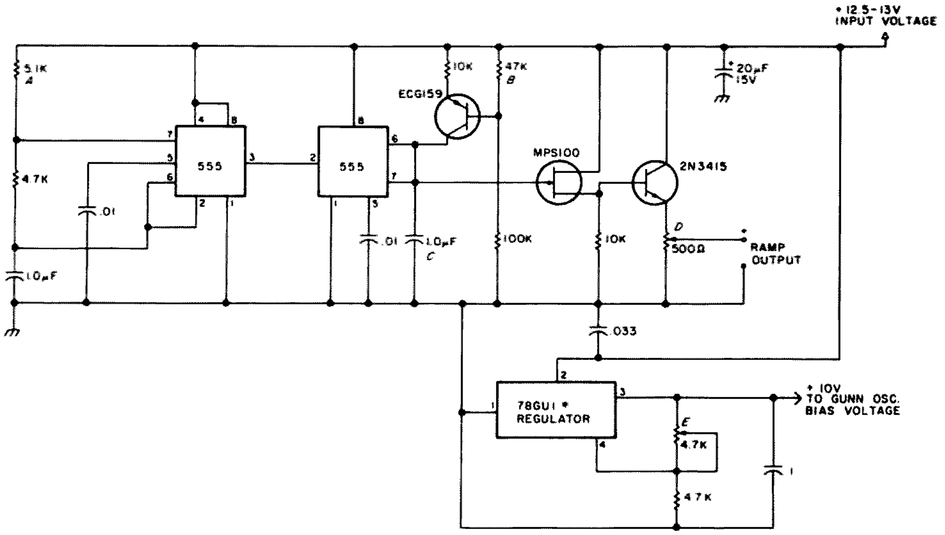

Fig. 2. Sweep circuit and power supply for a swept-frequency Gunn oscillator.

Considerable care in setting up an antenna range as described must be exercised. It must, at my location, be arranged so that the transmitting horn is at right angles to the nearby highway (which is in view) so that jamming will not occur to the Blue Wagons parked along the highway.

A block diagram (Fig. 1) of the test setup will give a good idea of how to apply the sweeper circuit to a similar Gunn diode setup. A Gunnplexer is used in the amateur band receiver, but without the oscilloscope since mountaintopping is hard enough without the weight of my old Tektronix 535. The circuitry shows how it is all done, with emphasis on sweeping the transitting oscillator's 50-milliwatt output. The use of a higher-power Gunn oscillator is anticipated which will increase the transmitting distance.

Let's take a look at the sweeper circuit (Fig. 2). It consists of a pulser keying a monostable oscillator to produce a very linear ramp voltage. This voltage is fed into a source-follower because the output of the ramp is taken from the junction point of the timing capacitor, C, and its switch. This is a fairly high-impedance point and loading can destroy the ramp linearity. The FET source-follower is fed into an emitter-follower which provides the output voltage and current required to drive the varactor tuning over the required voltage excursion.

The two integrated circuits are 555 timers. One is connected as an astable oscillator to produce the trigger pulse for the second 555 which is connected as a monostable circuit. The timing of each of these units can be made adjustable and some further description will assist in deciding how fast it should be made to sweep.

A 50-milliwatt Gunn oscillator swept over a 100-MHz frequency band in 0.8 seconds would cause only small problems to any kind of radar since the time on a particular frequency would be only a very small part of the sweep time. But I needed an oscilloscope presentation and, of course, a faster sweep, at least a 30-Hz rate. A sweep rate at this speed will draw little attention to its originator because it is below the radial velocity of an X-band signal.[1]

This velocity factor, 31.4, multiplied by the desired detection speed of a radar determines the rate which is used for the display system of the radar. Example: 1884 divided by 31.4 Hz equals 60 miles per hour. So, if the swept rate is less than 31.4 Hz, it will not indicate because most police radars are calibrated to plus or minus 1 mph. The radar receiver, of course, will detect the signal, and, in fact, it may just jam it so that it cannot indicate any speed. The best way to use this device is keep it pointed away from roads and highways when tuning up your radar detector.

The circuitry shown uses all fixed values so that the sweep frequency will be below the radial velocity described. The components marked A, B, and C can be changed to suit the needs of the constructor. Resistors A and B can be potentiometers and capacitor C will have to be changed accordingly. Consultation of data sheets[2] for the timing rates for the monostable and astable circuits will save considerable time in choosing the right values.

The MA 87125 varactor-tuned Gunn oscillator transceiver used in the swept-signal source requires 650 milliamperes of current for the Gunn diode bias. A circuit shown as part of the sweeper circuitry, marked bias regulator, will provide ten volts maximum at the desired current for this purpose. If a greater power output Gunn unit is used, a larger regulator will be required. A 78-series regulator will handle currents over 1 Ampere.

The circuitry shown was built as a breadboard on a small piece of perfboard with flea clips serving as solder points for the components. No particular care was given to parts placement and no problems were encountered with the circuit wired in this manner. Several other units were made to be used mobile and were mounted on a printed circuit board manufactured by Peters Publications, PO Box 62, Lincoln MA 01773, and will be available shortly at a moderate cost.

When construction is complete, it is advisable to make the following simple tests without connecting the Gunn system to it. To do this, apply 12.5 to 13.5 volts to the input voltage terminal. This voltage can be supplied from an automo-

bile storage battery or any convenient source. If a vehicle battery source such as a cigarette lighter jack is used, additional filtering is needed to keep out alternator or generator whine. Adjust potentiometer D to provide a reading of 4 volts as indicated on a voltmeter. This will guarantee that the sweeper starts off at the center of the tuning range of the varactor tuning system for the Gunn oscillator. Next, adjust potentiometer E to indicate 10 volts at the point indicated for the Gunn diode bias voltage.

You may now connect the transceiver to the sweep circuit card. Be sure that you remove the dc supply while you are connecting the circuit to the transceiver. This unit costs considerably more than you want to throw away by blowing a Gunn diode or varactor with a spike caused by a soldering iron or some other fluke.

When all connections are completed and you are sure of them, turn on the dc supply. You should be able to detect rf output from the Gunn oscillator with an rf detector. If none is available, connect a voltmeter to the Doppler output solder pin and terminate this point with a 500-Ohm resistor. When the Gunn diode is oscillating, the correct output voltage should be 0.2 volts across this resistor. If it is higher, adjust the screw found in the waveguide flange (just behind where the antenna connects) until the 0.2 volts appears. Make sure the antenna is pointing away from reflecting surfaces when making this adjustment.

Now that these adjustments have been made, you can be certain that the oscillator is sweeping from 10.465 GHz up to 10.525 GHz. With the voltmeter connected across the varactor tuning pin, readjust potentiometer D so that the meter now reads 8 volts. With the voltage set at this point, the ramp will pull the oscillator through its range and sweep approximately ±60 MHz either side of the center frequency according to the manufacturer's specifications.[3] The sweep linearity is considerably better than the tuning linearity of the varactor diode, so bunching up of the swept frequency will exist on the high end. A small jump occurs at the low end which is caused by the breakover point of the same diode, also contributing to a nonlinear start of the ramped frequency.

When using this device outside or in a vehicle, it must be remembered that the oscillator is subject to temperature problems as is any free-running oscillator for which temperature compensation has not been made. The manufacturer states that these units are tuned at the factory to the specified center frequency ±5 MHz with 4 volts on the tuning varactor, and that the electronic tuning stability is −350 kHz per degree C. With this information available, it should be evident that the sweep frequencies available from this unit are seriously affected in the New England weather, so in the winter the antenna range is not in use and 20 meters is again my meat. ■

Battery Check!

—do your nicads measure up?

Once upon a time, I was sent two boxes of AA cells for use in a pair of HTs. Both of the HTs received well after the cells had been installed, but only one would transmit. Swapping battery packs revealed that the problem was in the batteries, not in the HTs. The relatively low drain in the receive mode was supportable; the high drain in the transmit mode was not.

The solution was to grade the cells, using the setup shown in Fig. 1(a). This test is similar to the lead-acid cell tester which used to be used before car batteries were sealed. See Fig. 1(b) for this antique device. Caution: Do not test any high capacity cells this way with a VOM. Be sure your VOM will handle the peak currents shown.

Short-circuit currents for three common sizes of carbon-zinc cells are shown in Table 1. These are typical and may vary. Note that extended testing is self-defeating. About 5 seconds should be enough for you to take a reading.

The trouble with cells is that they all have some amount of internal resistance (R_{int}). When this is low in relation to the load resistance (when the HT was in the receive mode, for example), then it may be ignored. When the internal resistance of the cell is high in relation to the load, as with the HT in the transmit mode, then most of the cell voltage will be dropped across R_{int}. The load will receive only a fraction of the total cell voltage and the load current will be limited by R_{int}.

In the case of a battery of several cells, as in the HTs mentioned, one or two bad cells did render an entire pack seemingly useless. "The batteries are dead." Really, it is better to say, "Some or all of the cells may have a high internal resistance." More words, but cheaper than replacing otherwise good cells.

Internal resistance increases with the age of any dry cell. This is why the term "shelf life" is used. Most cells will always measure full *voltage,* even near the ends of their useful lives. Only really fresh cells will deliver full *current.*

Finally: The subject of this article is the testing of carbon-zinc dry cells. Alkaline, nicad, gell, and lead-acid cells should be tested with discretion. For high capacity cells, a circuit similar to Fig. 1(b) with a low value resistor at R1 could be used until you have some idea of what the peak current will be. Be kind to your meter! ■

D	3.3 A
C	3.7 A
AAA	2.7 A

Table 1. Short-circuit currents for three common cell types.

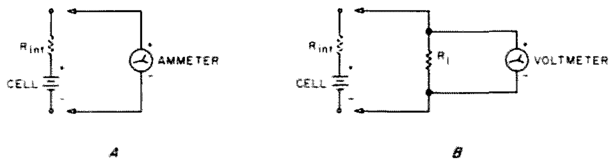

Fig. 1. Cell testing with a VOM (a) and an automotive cell tester (b). R_{int} is shown with dotted lines because it is invisible in most cases. This is discussed in the text. R1 would be perhaps 0.01 Ohm for an automotive cell tester, and from 1 to 10 Ohms for typical amateur applications.

LETTERS

TURKEYS

The article "Wild Turkeys 1, FBI 0" (August) was one of the most informative general interest stories i've ever seen in a ham publication. Mr. Howard seemed dismayed, however, that the individuals suspected of planting the remote jammer were not prosecuted. I would like to offer the following thoughts on the matter:

What if the FBI had already staked out the jamming site when Mr. Howard and his two friends first attempted to locate the transmitter? And what if the club members had found the transmitter, and then were approached and questioned by the FBI agents? Again, here are some licensed hams in the vicinity of an illegal transmitter, only instead of hunting coyotes, they are "trying to find a jammer, so they can put it off the air." No, Mr. Howard, without any more than circumstantial evidence, the Feds were right in refusing to prosecute the suspects.

Bob Morrow WB6GTM
Palo Alto CA

The title you selected for the article on page 12 of the August issue of *73* ("Wild Turkeys 1, FBI 0") reflects your prejudice and shows, I believe, a shameful lack of journalistic integrity.

Anyone reading only the title would have thought that the FBI really goofed up badly. After reading the article, one finds it was not the FBI who goofed up, but the FCC and perhaps the US Attorney.

Being somewhat curious, I contacted the author of the article, who advised me that he thought the FBI did a good job, and that, in fact, he had sent a letter of appreciation to them for their assistance. He also said the title he submitted for the article was "The Wily Coyote Hunters." In his opinion, it was the FCC that was the "paper tiger" in this case.

If we really seek to encourage the FBI in the pursuit of jammers and other illegal radio operations, I think praise and some thanks are in order. Heaping unfounded criticism on them is not likely to help our cause. If you must cast stones, it would appear you could find a more deserving target.

Steve Russell W0OGJ
Freehold NJ

While we appreciate the efforts of the FBI on behalf of the amateur community, we still stand behind the title we chose. The FBI, as our country's most powerful law enforcement agency, must bear the responsibility for educating its agents in the art of gathering evidence for successful prosecution. Considering the FBI's annual budget, we have a right to expect more than good intentions. Should we criticize the FCC for not prosecuting a case in which the only evidence was highly circumstantial? The FCC is to be congratulated for refusing a case that could only have wasted taxpayers' money. Individuals in our society are still innocent until proven guilty. May it always be so.—KA1LR.

NICKEL QSLS

Wow! That's a great idea on QSL cards. I need California on 20m SSB. I think a nickel is about right. Here's my check. Please hurry!

Larry Buhrman WA4GKG
Chattanooga TN

No split orders.—Wayne.

A SIMPLER WAY

In reference to the article titled "Solar-Powered Alignment Tool" in the August *73*, there is a way to determine a north-south or east-west line from the sun without the use of tables, clocks, calculations, etc., as are needed in said article.

The method requires only a small area of relatively level ground and a stick (two or three

feet long) stuck into the ground or other similar device that will cast a shadow so the shadow of its top can be spotted on the ground. One marks the top of the shadow, say with a small rock, at one time and then a couple of hours later marks the top of the shadow. A line through these marks will lie in an east-west direction quite accurately.

If one should wish to determine the time of local noon, he could construct a line perpendicular to the east-west line; that is, a north-south line. Then a stick could have one end stuck into the north-south line and lean over the line by the use of a plumb bob at the top end to align the stick with the line. High noon will be at the time the shadow of the stick exactly falls over the north-south line.

At this time the boom of an antenna can be given a north-south alignment by turning the boom so its shadow and that of the mast line up.

The above method of determining direction was discovered by a very young boy twenty or thirty years ago.

Fredrick Ketterer KA4IYV
Elberta AL

Shades of Stonehenge!—Wayne.

RADAR ROUNDUP

Glad to see that you haven't forgotten about Big Brother's foray into the world of electronic enforcement, and our attempts at passive electronic countermeasures.

I recently had the pleasure (?) of spending a total of 24 hours driving time between Cincinnati and the nation's capital, averaging 55 mph and including a few stops. Aside from sheer distance, the next most irritating factor was the 55-mph speed limit. This time I made the trip in a VW Beetle, so I felt no urge to push it past 55, but we do have faster cars in the garage and 55 in one of those would have been all the more unbearable. In that distance, the difference in time between 55 and 70 mph is approximately 1 hour and 10 minutes on one leg of the trip—a good deal of time that could be spent not trying to stay awake at the wheel (that leg was 10 hrs at 55, the other leg being considerably longer due to a side trip).

If I make any money on that

trip, then I'll consider billing the government at an according hourly rate for those 2 hours and 20 minutes.

I learned a few other things: Radar detectors are not permitted in motor vehicles in Virginia, but at least they warn you of that at the border. Maryland enforces their speed laws. West Virginia apparently doesn't. Pennsylvania certainly does—they had plenty of troopers out taking radar readings, while perhaps one mile down the road (the PA turnpike), some poor motorist was stranded and displaying a white cloth as the little toll ticket instructed him to do. The troopers seemed more interested in making money though, and they must bring in some great sum, for the fine for doing 56 to 60 mph was $45.00! The sign said "Radar for your protection," but it should have read "Radar for our profit." Finally, I learned that two-meter radios can interfere with radar speed devices when, as I drove by one trooper taking readings while I was in conversation on simplex, the trooper threw his arms up in disgust and walked back to his car. This phenomenon happened several times—that's what they deserve for purchasing such shoddy equipment.

It seems that using a device for radio detection and ranging to enforce the speed laws is in poor judgment, due to the nature of the system and possible inconsistencies that might arise from improper use of this system by law enforcement agencies. Let radar be used by the DOD and the FAA, and let the police and Highway Patrol use stopwatches.

Until that day, keep up the fight against government injustice, or this alleged government for the people will become a government against the people. (People in Virginia should keep a Kleenex box on their dashes.) I've done more dangerous things than driving 70 mph. How about you?

Marc A. Boone WD8ROA
Cincinnati OH

You're just baiting me.—Wayne.

REVERSE RADAR RAP

I am an avid reader of your editorial columns and never miss an issue. I am always checking for the latest information that you have about radar. I have some information that I think you should tell your readers about.

First, any crystal-type radar detector will modulate the return radar beam, with a frequency of between 45-55 mph, if the radar detector is within 100 yards of the *police* unit.

I purchased an old "speedalyzer" radar unit at a swapfest and ran some tests with it on my bench. I found out that the microwave diode in the radar detector causes a "chopping" effect and passively chops the return beam up in little pulses. (Signal comes in, diode conducts, shorts out waveguide, no signal. Diode unconducts, signal appears again, starts all over.)

What this will do is that if anyone is driving normally, at a speed below 50 mph, and passes a squad car, it will cause the police radar to read 50 mph regardless of what speed the car is going (provided it is going slower than 50 mph).

The worst part about this is that the units do it even when they are turned off (since the diodes require no power).

Please caution your readers about this problem. I got a speeding ticket because of this problem and it took me 3 years of fighting before I got it dropped. I threatened to go to a jury trial, with all the press, and demanded a test run to show them that I could make their radar read any speed that I wanted to without my car moving an inch.

The court DA said that they couldn't stand the publicity and didn't want the hassle of all the people demanding their money back, so they threw it out of court.

Other people might not be so lucky and have to pay the fine, not realizing that their radar detector was to blame.

Ken Slate W9ITW
Ripon WI

Troublemaker.—Wayne.

MONEY FOR SCHOLARS

The Ed Redington Memorial Scholarship Fund, established last year in honor of W4ZM, has continued to increase. It is

hoped that sufficient funds will be received to establish a perpetual scholarship in Ed's memory.

Many individual and club contributors have indicated that they expect to make annual contributions to the fund in order to spread their tax deduction over a longer period. This is to remind them that it is now time for their 1981 contributions.

With the fund still short of its goal, it is hoped that many others will follow the lead and make additional contributions this year and in coming years to ensure a sustaining fund for this worthy cause.

Won't you help us reach that goal? You may wish to suggest additional contributions at your next club meeting. Everyone who knew Ed appreciates the value of this living memorial to him. Donations in any amount will be most gratefully accepted and acknowledged. Send your contributions to: Foundation for Amateur Radio, Attn: Ed Redington Scholarship Fund, c/o Richard F. Vincent K3AO, RFD #1, Box 230, Bryantown MD 20617.

Bill Miller K4MM
Fairfax Station VA

PARIAH

I read your editorial in the June edition. I wish I could express my thoughts on paper.

I agree with you on the way the ARRL operates. I am a member of ARRL and one of their clubs.

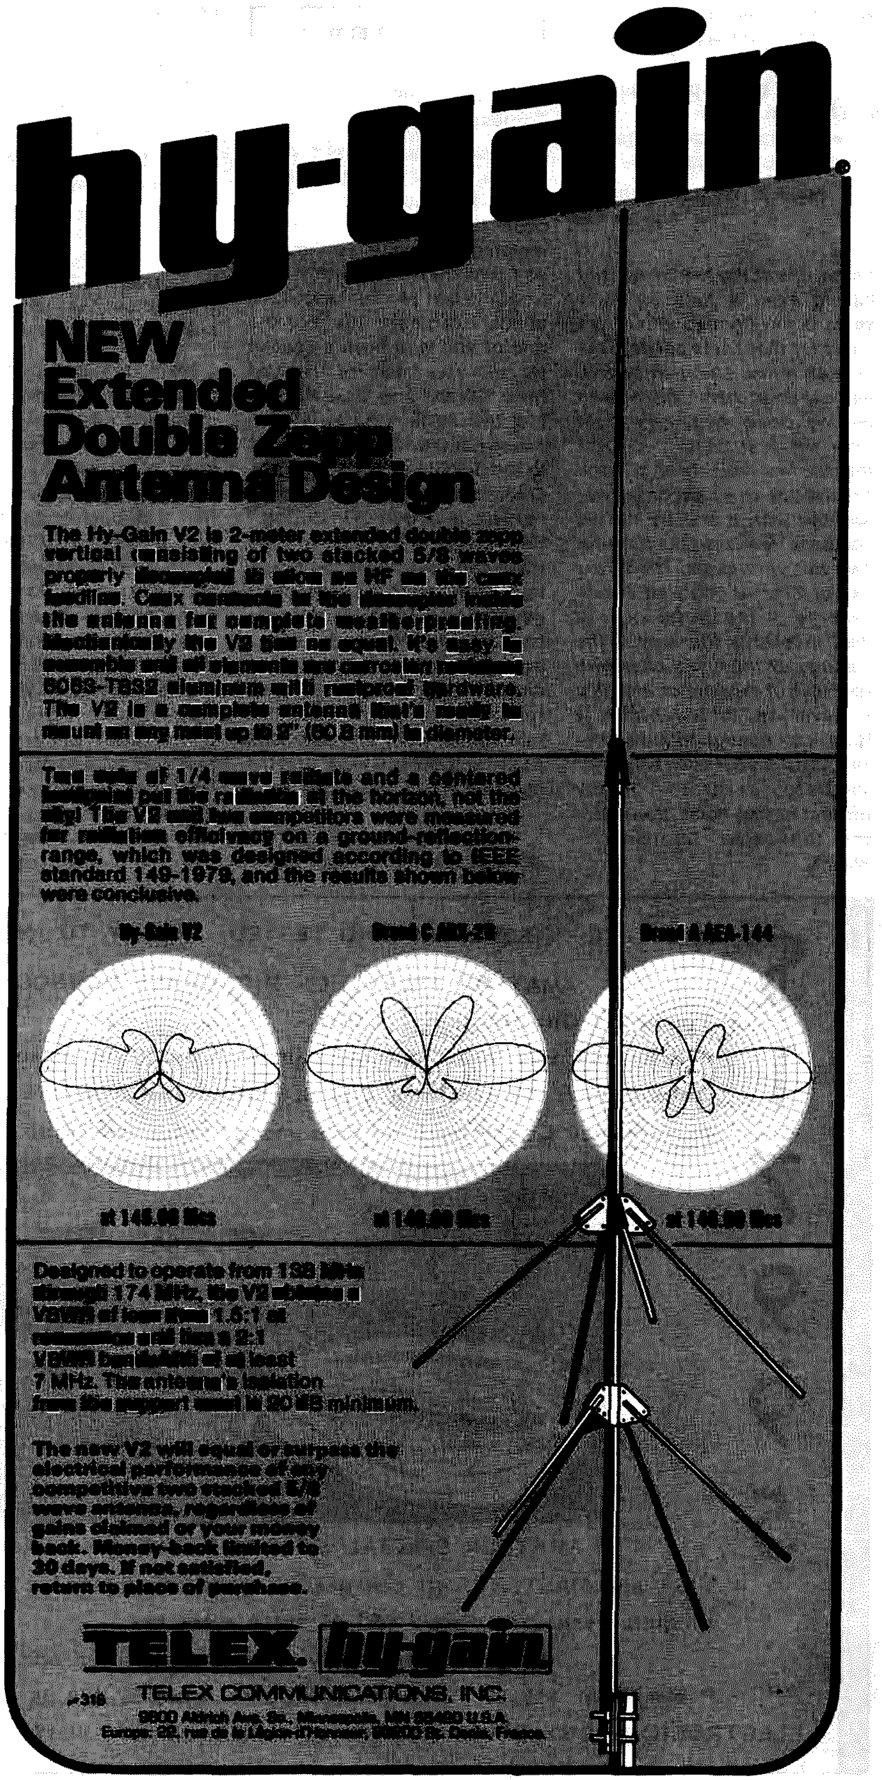
What I want to know is where is the courtesy and good fellowship the hams used to have? The CBer has more fun and courtesy than the hams of today.

If you are a novice you are ignored and can't even get into the clique. The ARRL has a magazine that takes an engineer and a computer to figure out. I thought ham radio was supposed to be fun and a hobby—not engineering.

The lifeblood of any organization is the lowly novice. Where are the "Elmers" they talk about? I need help and have been ignored by the snobs in the club. There isn't too much for the novice in the magazine.

Your magazine is in plain language. Even if you talk about a General class, you name the person and not a lot of numbers.

The hams are getting rude



and discourteous on the air. I was told to get the hell off the air till I learned.

I better shut up because I could go on and on.

I enjoy reading your magazine and hope to continue to do so.

Frank D. Windsor KA6OPZ
Agoura CA

Frank, one of the few benefits of having been a ham for forty years is having read letters like yours for that same period. This may be a new situation to you, but old-timer hams have been putting down beginners right from the first days. I suspect that the first ham sneered at the second one as a newcomer. You just live with it and try to find someone newer to take out your own frustrations on. The bright part of it is that only a small percentage of the hams express their insecurity this way... the majority of them will bear with your lack of experience and help you over the first tough days. It is difficult enough to get on the air and have your mind blank out completely as to what to say without having some clown give you the pariah treatment.—Wayne.

RESURRECT ELMER

(Reprinted from the National Contest Journal.*)*

Elmer is dead. That's right, friends, Elmer and H. Scratchi and L. E. Rapp appear to have gone to the big Wouff Hong meeting in the sky. To those of you who have no earthly idea what the last two sentences are about, I dedicate this. For the rest of you who have a special place in your heart for "The Old Sock," 6L6s, and Blue Racers, bid those days farewell, because ham radio has evolved into the day of the Fox-Tango, the green stamp, the 8877, code readers, and "you're in the log." Before you throw this into the trash can next to the commode, let me tell you that I know every generation in the history of man has criticized the next generation, and the younger group doesn't want to hear any of this rot, but, read on, because this tale comes from one who isn't so old and conservative, and the scenario is sad, to say the least.

Ham radio was born of traditions of fellowship that make it unique to nearly every other form of human endeavor. Those traditions are not being passed along, causing hams to become as selfish and nondescript as the rest of our society. When many of us started in ham radio we had an "Elmer." Typically he was a middle-aged man who talked softly, never worked phone, didn't care much for DX or contests, and encouraged you without ever letting you do anything the "easy way."

He made you study, make mistakes, find your mistakes, fix them, and sweat your tail off to get a two-tube transmitter operating. Along the way, he instilled in you a pride and sense of tradition, a belonging, an obligation, and a respect of ham radio. Night after night you would sit on 7.172 trying to work 200 miles, while he was able to talk clear across the country with his 200 Watts and tribander! When you told him about your first DX contact, both of you lit up with pride. When you worked your first contest and made 62 Qs in 48 hours, you felt like you really did something. You did—you paid your dues!! The privilege of using the airwaves was not taken lightly. That piece of paper you got from the FCC was more sacred than your mother's picture!

For those of you still reading this, it appears that in the late 60s the morality of the world went through a change and, unfortunately, so did ham radio. It wasn't just a normal generational change, but a mutation. The scenario for a new ham now goes something like: from CBer to Illegal CBer, to a collection of books and tapes with other CBers, to a Novice license. No more Elmer! The Novice rig is now a TS-520, a TH6 at 50', and a memory keyer. Then more books, more tapes, six tries, and, voilà, a General license. Once again the VISA card comes out and, in no time, it's a TS-830, a 3K, a 70' tower, and a processor. After three months on 20 sideband, you have the current breed of amateur.

"Hey, this DX station isn't on a list, what am I going to do?" "I paid three grand for this radio station—if I can't work him, nobody will." "You're transmitting on his frequency, you goddam idiot." "This is my frequency." It's sickening. The latest chap-

ter seems to be that since amplifiers are now available commercially that run five to ten kW, it's morally acceptable to use one. Before, you had to covertly build a pair of 4-1000s, and, somehow, that was immoral and unethical.

I sat in a DX forum recently and listened to one of the top DXpeditioners brag about how he lied, cheated, and intimidated people to get to operate from a semi-rare DX spot. Lawsuits are becoming commonplace in ham radio. Two-meter FM is one step from channel 19. I don't have a solution, but I do know that I really don't look forward to turning on the old radio any more. Contests have fallen into the battle of the bucks, the unethical power, the poor operating practice, and the lack of the amateur spirit. I hope that the Commission doesn't get so fed up with our problems that they deregulate us into nonexistence. Pray for the resurrection of Elmer.

Tom Taorimina K5RC
Houston TX

Tom . . . balderdash! One tends to see what one wants to see. And, yes, all of those horrible things you are seeing are there, but they are not as prevalent as you imagine . . . nor are they anything all that different. Tom, twenty years ago . . . before those awful 60s . . . we had Dxers going out and lying up a storm to get into rare countries. Some lied about where they were and the contacts still are all okay for the League awards. We did have a bunch of bad language . . . particularly in southern California . . . but that has died down in most parts of the country. Pileups are the same now as they were twenty years ago . . . filled with silly operators jamming the DX station because they can't hear him . . . fighting with each other . . . and so on. Tom, I've been at this hobby for 44 years now and I honestly see few changes overall. Oh, hams are building a lot more these days and more of them make an effort to keep up with technology than forty years ago, but other than that I can cover every complaint you have with similar beefs forty and fifty years ago . . . back in the "golden ages." All you have to do is read "The Old Man" in those faded pages of QST to know

Investigating Icom's 730

—quite a rig

Icom's initial announcement of the IC-730 high-frequency transceiver created a flurry of excitement among many amateurs. Here in an attractive and very small package was a transceiver boasting numerous features previously found only in larger and more expensive units. Could the pint-sized gem truly alter one's thoughts concerning small-sized rigs as "main station" units? Ponder that question while we take a closer look at this feature-stocked unit.

Prior to my acquisition of the 730, I studied the amateur transceiver market quite diligently. I felt that all-solid-state design was paramount yet also desired reserve rf output capability for ease of mind when operating high-duty-cycle modes such as SSTV and RTTY. The ideal transceiver would also have an interface port permitting external microprocessor control. Finally, I wanted a rig equally usable in my main station or in a mobile or portable installation. My inquiries during the 1981 Dayton and Atlanta conventions indicated the Icom 730 could easily handle these prerequisites. During the waiting period for the 730 to become available stateside, I carefully monitored a friend's problem with an IC-720, comparing factory concern and results against previous experiences with other companies. The results were quite impressive: Icom performed repairs within a two-day period and included extensive written reports when they returned the rig. Importantly, telephone conversations with Icom's technicians were always congenial and helpful. The prospect of dependable service was the final nudge to purchase an Icom.

The Receiver

The 730's receiver employs quadruple conversion and a double balanced mixer in its front end. That combination (18-dBm intercept point and .3-microvolt overall sensitivity) produced one of the most enjoyable receivers I've ever used. Since band and power-line noises often play havoc with the supersensitive receiver in my other transceiver, I "tee-connected" both rigs in parallel for comparison. The 730 definitely received weak signals with better clarity and readability than my other unit. Wow!

Three tuning rates are front-panel selectable on the 730. The 1-kHz rate zips from one band edge to the other in three or four dial spins, the 100-Hz rate is approximately equivalent to the Kenwood TS-130's, and the 10-Hz rate (10 times slower!) provides massive bandspread for shaking fingers.

The 730's i-f shift is unique in two respects: It's tuned with a slider pot and *it really works*. I had expected the rig's optional passband tuning to be vital for my personal use, so I was quite surprised and pleased with the i-f shift's ability to dodge adjacent channel interference. It's great, particularly when used in conjunction with the receiver incremental tuning. The optional passband tuning, incidentally, is implemented when the 730's optional narrowband i-f filters are installed.

A dual MOSFET rf preamp which provides approximately 10 dB gain is front-panel selectable. This flexibility, when used in conjunction with the internal noise blanker, allows me to enjoy operating 20, 15, and 10 meters when my other rig is purely overcome with noises. Too much gain can, indeed, be more detrimental than not enough gain—in any rig. The 730's noise blanker, incidentally, can be switched between wideband (line noise and woodpecker) and narrowband (ignition and pulse noises). The fast agc in most transceivers is too quick for my use—they pump and drive the S-meter wild. The 730's agc, conversely, operates smoothly on either slow or fast agc.

All the new WARC bands are, naturally, included in the 730, although 160-meter coverage is omitted. WWV reception is provided in the 10-MHz band.

The Transmitter

Since I'm actively involved in full-duty-cycle modes like SSTV, I'm squeamish of solid-state finals which strain to produce full output. The 730,

The Complete Idiot's Guide to DX

The Complete Idiot's Guide to DX, *by Stuart Gregg NF4Z, Bash Educational Services, Inc., 1981, PO Box 2115, San Leandro CA 94577*

Many hams think of DXing as a part of our hobby that only the elite can enjoy; reading the various DX columns and newsletters leaves the impression that the only way to work the world is to have giant antennas atop gigantic towers and to run the legal limit and then some. And even if the hardware is available, the expertise isn't. DXers keep their secrets to themselves and speak a strange language of their own for which translators are hard to find.

The recent sunspot peak produced a lot of new DXers and reduced the number of people who thought that a monster station was a necessity for successful DXing, but the lack of information for the newcomer still remained. Now that we're on the downhill side of Cycle 21, it's even more important to learn the tricks that let the big guys work the rare stuff when the sunspots aren't helping.

Nowadays, most budding DXers learn by doing, and the process is sometimes a very unpleasant one for the rest of us in the pileup. The *real* lids are enough to keep us busy without having also to worry about ops who simply haven't yet learned any better. It's not the newcomers' fault—the problem is that there just haven't been any good books that provide enough information in one place to allow a beginner to jump into the fracas without fear.

The lack of DX textbooks won't be a problem for long. At least two new books aimed at the fledging DXer have been published recently. One, *The Complete Idiot's Guide to DX*, by Stuart Gregg NF4Z, is quite good if you take the title seriously. It *is* a guide for the total newcomer to DXing. If you've worked 200, or even 100, countries, you won't find much new here, but if you've just stumbled across your first pileup, *The Complete Idiot's Guide to DX* will tell you what's going on and how to make the best of it.

Author Gregg starts from the premise that the reader has never worked a DX station before and goes through a step-by-step description of how to make the contact. He describes both the traditional method of DXing and the more recent innovations of DX nets and lists. He wisely avoids getting involved in the controversy over these methods, and instead limits his comments to the mechanical details of how lists and nets work.

The Idiot's Guide contains a lot of good, solid information for the beginning DXer. It also has some problems, as any first edition of a book covering such a complex subject will.

The book's discussion of station equipment attempts to point out that modest antennas and medium power will do a good job, but some of the anecdotes Gregg tells us leave the distinct impression that it's a lot more fun to have a California kilowatt. Gregg points out the advantages of CW operation but misses the main one—that a "little-gun" station has a much better chance of getting through on CW than of battling through the QRM on phone. Although the book admittedly is not about antennas, it would be nice to see some hard information on simple antennas that will work DX. Such creatures do exist, but the thrust of Gregg's discussion is simply that if you can get away with it, bigger is better. That's not much comfort for those of us who *can't* get away with it!

These are minor, perhaps philosophical, problems. But there are some things that a book on DX must have that this one doesn't. For example, there is no reference to the importance, nay, the absolute necessity, of using GMT (or UTC) time on QSL cards. The sad fact is that if your card doesn't carry the right time, in the right format, you are very unlikely to get one back from a DX station. Anyone who's ever handled cards for a DXpedition or contest can vouch for the pain that it is trying to find a QSO for which the time isn't accurately shown on the card.

The listing of operating events includes several small contests I hadn't heard of before, but misses both the IARU Radiosport

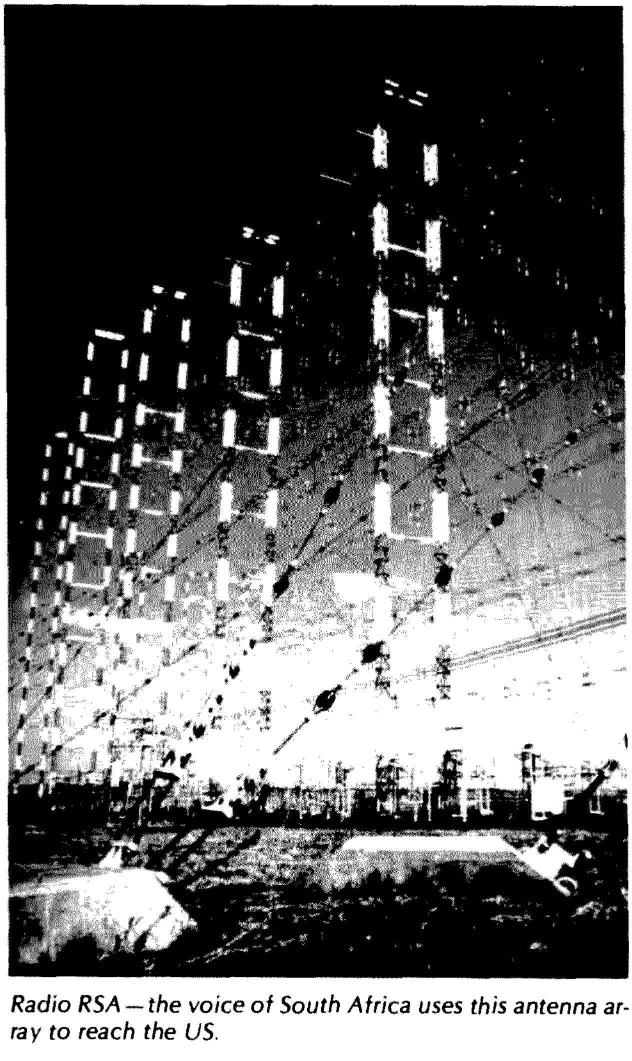
Eyeball QSO with Radio RSA

Roger N. Peterson
25 Orchard Lane
New Canaan CT 06840

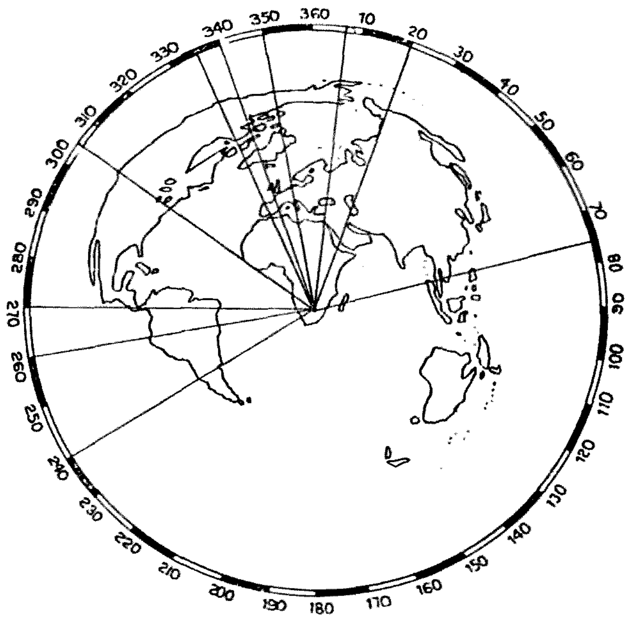
Have you ever dreamed of visiting that faraway, exotic country whose radio station you are listening to on your receiver? I'm sure you have. We all do. This time, however, I did something about it.

I was tuned to Radio RSA—the Voice of South Africa—and was enjoying a program called "Touring Africa." It was all about the famous Krueger National Park there, where visitors drive around in British Land Rovers to view the elephants, lions, rhinos, and other wild animals that roam free and without danger of being shot at by hunters. Listening to this fascinating program got me interested in seeing all this for myself. It would certainly be a switch from the usual Florida or Caribbean island vacation that so many of us from the northeastern part of the US aim for in the winters.

So here I was, a few months later, being driven through the streets of Jo-

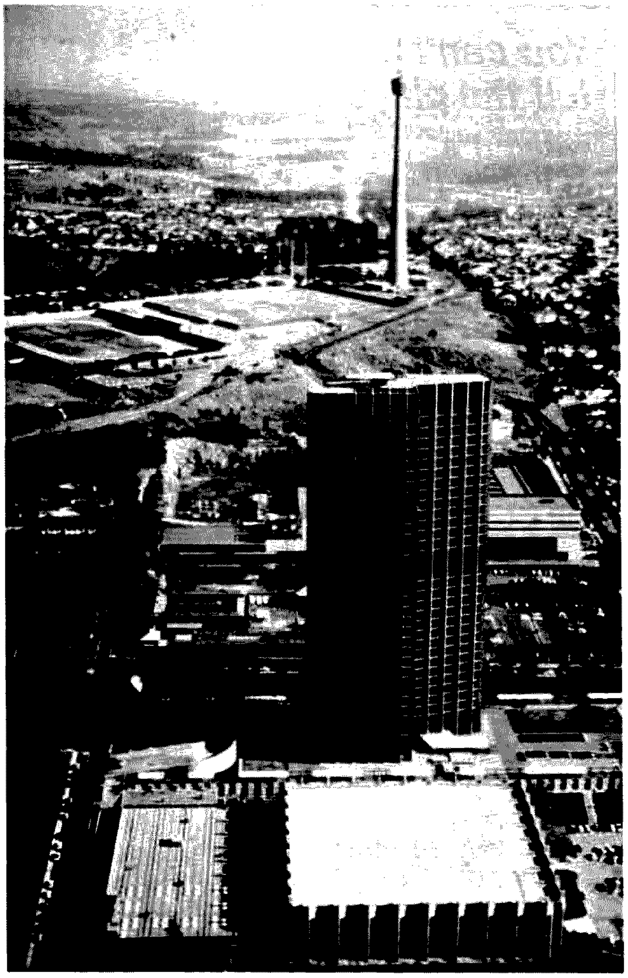


Radio RSA—the voice of South Africa uses this antenna array to reach the US.



This great circle map indicates the general broadcast directions for Radio RSA's Meyerton transmitting station at its center in South Africa.

Antenna side-switching hut showing a portion of antenna routing system. Each "square" is a motor-driven switch.



Broadcasting center of Radio RSA in Johannesburg. Large tower in back holds FM radio antenna.

hannesburg, the largest city in South Africa, by Pieter Martins, the principal engineer of Radio RSA and host of the station's popular DX program.

This had come about simply because when I made my travel arrangements, I also wrote a letter to Pieter to try to arrange a visit to Radio RSA. So on this day, Pieter had picked me up in his car at my hotel and was starting the visit with a trip out to view the transmitters and antenna installation located about thirty miles south of the city.

As we drove out of the city, we passed huge manmade hills, piled up from years of gold mining in the area, and several block houses which dated back to the Boer War. As we got nearer to the installation, I spotted some tall steel masts, and when we entered the village of Meyerton, I saw a multitude of these high masts towering into the blue African sky. Not much like my own antennas, strung between two trees in the backyard of my Connecticut home!

Ultra-Modern Transmitter and Antenna Installation

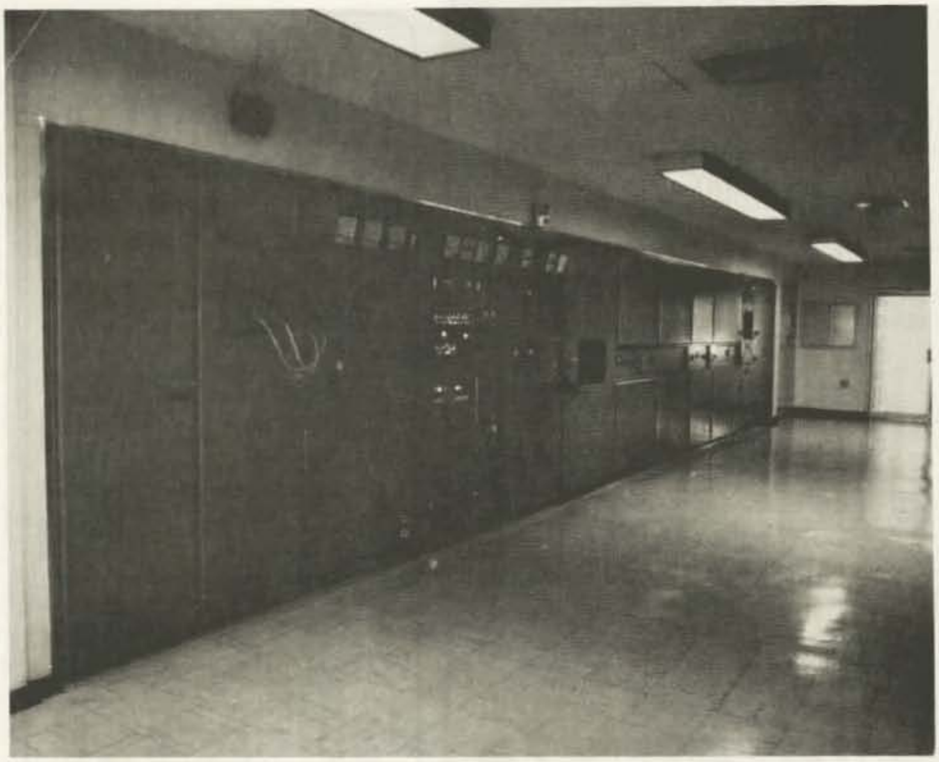
We parked the car and entered the main transmitter building. This structure has an antenna side-switching house and contains the consoles that control the transmitter tuning, antenna selection, and slewing. There are three 500-kW and four 250-kW transmitters. The larger ones had only recently been installed (spring, 1979) and were responsible for booming a big signal into the US in recent months.

Pieter explained how, from the consoles, by the pressing of a single switch, the powerful transmitters could be coupled to any of the station's 34 respective high-gain antenna arrays to cover any of Radio RSA's target areas. These consoles have preselection facilities so that a new frequency and antenna with appropriate orientation may be selected in seconds.

The transmitters have an interesting cooling system. Cooling is by a vapodyne system which utilizes the latent heat of steam. This system uses a small amount of distilled water and eliminates the need for old-fashioned water pumps. The steam is condensed on the mezzanine level of the building by heat exchangers and returns to the transmitter tube anodes as water. From there it is once more circulated in the closed cooling system.

From the top of the large transmitter cabinets, the feeders go by way of crossbar switches in ducts down vertical shafts which connect up with two tunnels and then to the round antenna feeder side-switching house. This unique system of an underground route for the ducted feeders had to be used due to their large surface area. This would have presented a hazard in strong gusts of wind in the case of overhead feeders.

The radio feeders enter the feeder switchhouse along five horizontal rows



One of the 500-kW transmitters.

of switches. These feeders are switched vertically and leave from the top of the building to the appropriate overhead feeder and accompanying antenna.

Each of the directional antenna arrays on the 500-hectare site consists of two curtains spaced a quarter of a wavelength apart. Each curtain is made up of three or five stacks of four half-wave dipole elements in a chain. When power from the transmitter is fed into the front curtain, radiation from the individual dipoles is additive in the direction of the main listening zone, the total power gain achieved in some instances being as much as 20 dB. The antenna arrays have seven general directions (see Fig. 1). By phasing, it is possible to swing the beam electronically 15 or 30 degrees away from its center position to direct a transmission to a different target area. The general directions are 335° and 340° for West Africa and Europe; 76°, 20°, and 7° degrees for East Africa and the Middle East; 305° for North America; 240°, 260°, and 270° for South America, and 350° for Central Africa.

As we left the transmitter and antenna installation and drove back toward the city, Pieter described the South African Broadcasting Corporation organization and headquarters complex. Radio RSA is the External Broadcasting Service of the S.A.B.C. Other services include television and FM radio. Some of you may have DXed Springbok Radio and Radio 5 in past years. These are both part of the S.A.B.C.

This complex is located in the Auckland Park section of Johannesburg, a primarily residential area. It looks like a college campus, with its 40-acre area, two high structures, and a number of two- and three-storied buildings which house studios. The dominant structure is a 55-story tower which houses the FM antenna. Facing this is a large, multi-storied office building. This complex houses facilities and staff to broadcast 16 radio and 2 television program services, totaling 2,317 hours a week in 18 different languages.

The building which houses Radio RSA is very modern and contains all of the latest broadcasting equipment. Because of all the different language broadcasts, the staff personnel that you see in the corridors and studios make you think that you are in the halls of the UN building in New York City. For example, the Lozi language announcers all come from the Caprivi area in southwest Africa. The Swahili and Chichewa announcers hail from Malawi. In other language services, the announcers are either South Africans or people who have been recruited from Europe. Radio RSA also broadcasts programs in Dutch, Portuguese, French, German, Tsonga, Afrikann, and English. Soon, Radio RSA will add Spanish as they step up their broadcasting activities to South America.

Radio RSA Programs

There is much to listen to on Radio RSA. In fact, some people think it is shortwave listening at its best. First is the news. No other shortwave broadcaster covers the African continent like Radio RSA. They send out 42 news broadcasts a day, of which 7 are in English. In addition, they have a number of back-up programs to help the listener understand the situation in different parts of Africa.

News bulletins are written by Radio RSA News Department specialists and they have the resources of five international news agencies, regional news offices, and a network of correspondents in many parts of the world. Recently, a survey was made to find out what shortwave broadcasts African delegates to the United Nations listened to. Some three-fourths of them reported listening regularly to Radio RSA to keep informed of what was going on back home.

News, however, is not the only thing you will want to hear on Radio RSA. The station has many interesting programs throughout the week. I mentioned "Touring Africa"—the program that got me interested in visiting this country in the first place. This program is on once a week and will take you to all the interesting sights in South Africa: Capetown, perhaps the most beautiful city in the world; Durban, which is on the Indian Ocean and has some of the cleanest and whitest beaches I've ever seen; the Cape of Good Hope, where you see the Atlantic Ocean meet the Indian Ocean, and much more. You can hear this program on Saturdays at 2100 GMT and on Sundays (Saturday night in US) at 0200 in English.

Radio RSA broadcasts an excellent program every morning at 1300 GMT and also at 0300 GMT. It is called "Good Morning Africa" and while not directed to North America but to neighboring nations on the African continent, is easily picked up here in the US. It features short commentaries, live interviews, and music. Again, it is in English.

If you are interested in sports, Radio RSA devotes Saturday mornings from 1300 to 1500 GMT to various seasonal athletic games. This might be a professional golf tournament with Gary Player and other international pros. Or, it might be a rugby game or cricket match. As in Australia, South Africa's summer is our winter and vice versa. So don't be surprised to hear a ski meet from the Drakensberg Mountains in July or a surfing contest from a beach on the Indian Ocean in January.

Some of the most interesting programs heard on Radio RSA are interviews with either famous or interesting people. In fact, I feel that Radio RSA has the best interview programs of any of the shortwave broadcasters, including the mighty BBC. Try these on a program called "South African Panorama" on the English broadcasts at 2100 and 0200 GMT on Mondays, Tuesdays, Thursdays, and Fridays.

Just for DXers

If DXing the African continent is of interest, don't miss Radio RSA's "DX Corner" each week. This program is hosted by Pieter Martins, my guide, and he has a good one. From time to time, Pieter has guests who are members of DX clubs, hams, or visiting hobbyists from other parts of the world. If you want to keep up with the frequency and time changes of the African nations' broadcasters, this program is a must. You can hear it on Tuesdays at 1120 GMT, Saturdays at 2140 GMT, and Sundays at 0240 GMT.

Where to Tune In for Radio RSA

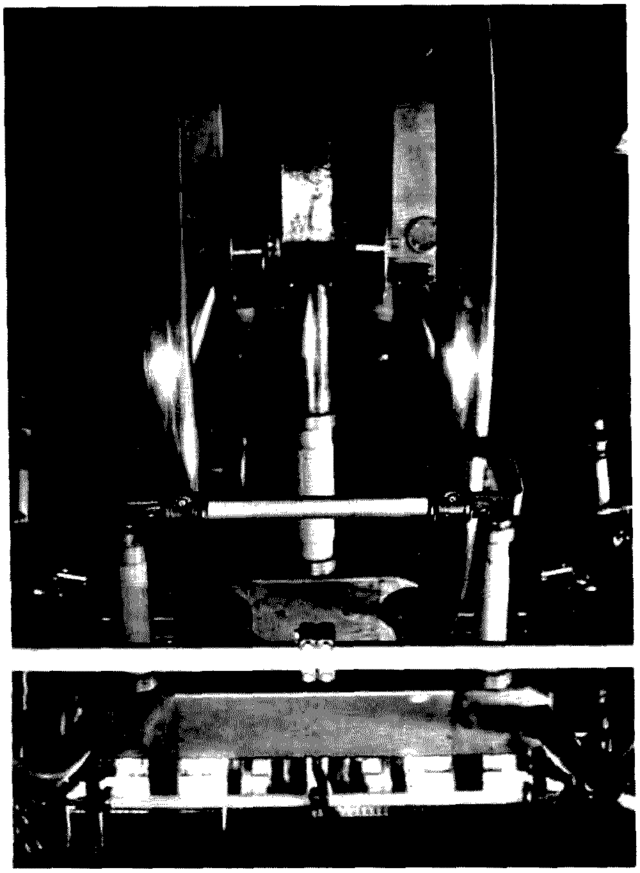
This station is on every day of the week in English. They direct their broadcast to North America at 0200 GMT on 11.900, 9.615, 9.585 and 5.980 MHz. However, their signal is so strong that you can usually receive them when their programs are directed to Europe or other parts of Africa.

In the late evenings here, at 0300 GMT, try Radio RSA on 11.900, 9.585, or 7.720 MHz. It is usually very easy to hear them. When you get up in the mornings, try them at 1100 GMT on 25.790 MHz, also on 21.535 or 15.220 MHz. At 1300 GMT, on the same frequencies, Radio RSA comes in even stronger and you should have no trouble at all in bringing their broadcasts in. Finally, in the afternoons at 2100 GMT, the station comes in loud and clear on 17.780 or 15.155 MHz.

Radio RSA broadcasts every day on the frequencies and times indicated above. You can obtain a program of their broadcasts by writing Radio RSA, PO Box 4559, Johannesburg 2000, South Africa.

Finally, what about the rest of my trip to South Africa. That, of course, is a story in itself. To those of you who have ever thought of going there, I can recommend it highly. In fact, I liked it so much that I hope to go back again for a return visit. That is, if some other exotic shortwave broadcasting location doesn't entice me there first.

I wonder what it's like in New Zealand? ■



Tuning coils for one 250-kW transmitter.

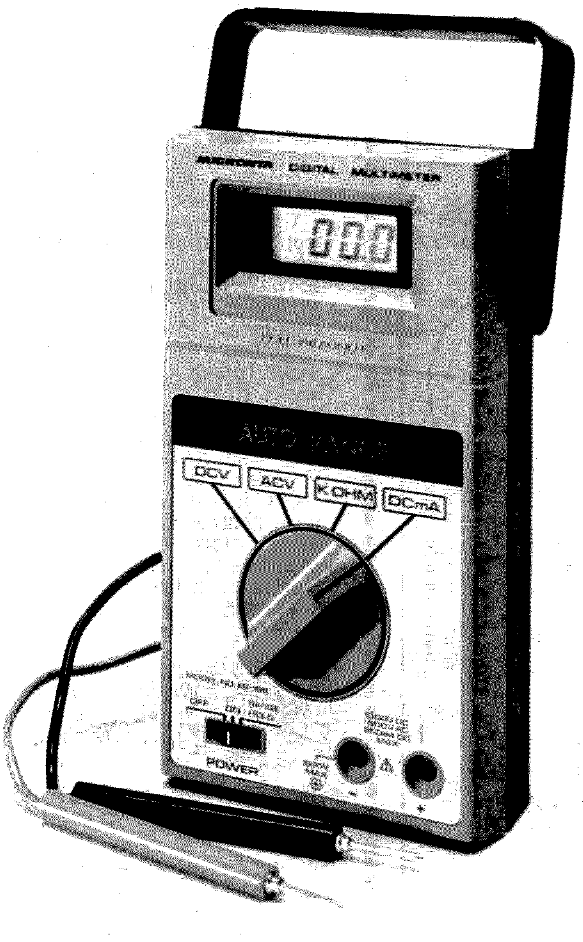
Micronta's New Multimeter

—an LCD DMM from T-RS



The Micronta LCD Auto-Range Digital Multimeter. (Photo courtesy of The Tandy Corporation)

Fred Blechman K6UGT
7217 Bernadine Avenue
Canoga Park CA 91307

There is little doubt that a multimeter is the most-used item of test equipment among hams, electronics technicians, and hobbyists. A typical multimeter measures current, voltage, or resistance in various ranges, depending on switch setting. Until recently, multimeters used common analog meter readouts—a needle moving along a marked scale. Then, not long ago, digital multimeters appeared. They read the value in LED digits. LEDs consume considerable power, so these instruments usually needed to be plugged into ac power or had short battery life.

With the advancement of technology, the LCD (liquid crystal display) is displacing LED readouts in most instrumentation, and many LCD digital multimeters (DMMs) are now available. Using standard alkaline batteries, many of these DMMs can be used continuously for hundreds of hours before battery replacement. This makes the units truly portable and independent of ac line transients and noise.

The typical LCD DMM uses either a rotary switch or a bank of push-buttons to select range and mode. First you must decide *what*

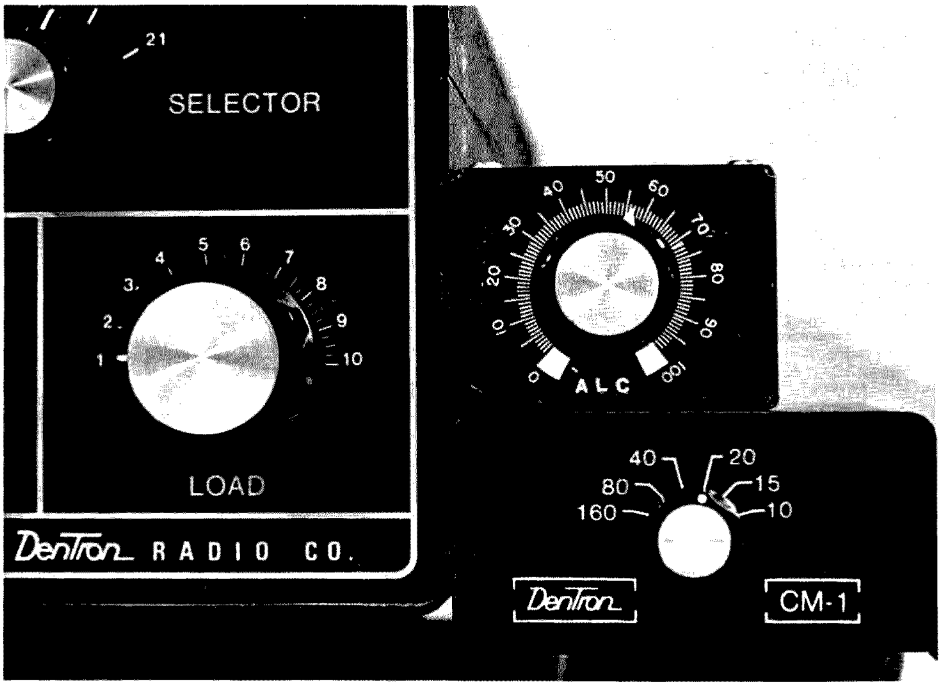
Mods for the Clipperton-L

—smooth sailing ahead

When my trusty old home-brewed linear gave up the ghost, I started to shop around for a replacement. Being a professional loafer, I had to watch the green stamps, so the first requirement was low cost. Since I am partial to 572-Bs (low replacement cost), the DenTron Clipperton-L looked like just what I wanted. After getting it home from the dealer, cutting off the ac plug, and rewiring it for 220 V, I hooked it up to my TS-820S and away we went!



Remote alc pot located on top of CM-1 accessory.

Wow! The pilot lights were *bright*; when you went to transmit mode, it looked like the sign on the local massage parlor! Realizing that this might keep me awake during round tables, I swapped the Power and Transmit bulbs with a type #327, a 28-volt bulb that gives reduced, but adequate, brightness and will last longer than the 14-volt bulbs supplied.

Next, I looked at the output waveform on my monitor scope. Ouch. There was hum on the rf envelope! But, running tests with local hams on both CW and SSB disclosed that the inadequate power supply filtering was no problem. This again proves that the average ham receiver has poor audio frequency response at low frequencies, especially with small speakers in inadequate baffles. So, I left it alone.

I started to compare notes with other Clipperton owners and found that they

had problems similar to those I am about to discuss. These findings are based on five separate amplifiers, so they are not just a fluke with my amplifier.

Of the five amplifiers, three soon developed noisy cooling fans. The objectionable noise changed pitch, indicating the fan was changing speed. This noise was blamed on defective sleeve bearings (a sleeve-bearing fan should be *quieter* than a ball-bearing fan) and replacement fans were requested from DenTron under warranty. They were sent without charge and were noted to be from a different manufacturer. *Warning*—Disconnect the power cord when working on the fan when the amplifier is wired for 220 V because the power switch disconnects only one side of the line.

Some of the fans had a heavy wire grille (to prevent you from sticking your pinkies in the rotating blades), while other fans had a fine-wire mesh grille, evidently intended to provide better rf shielding. The 4-1/2″-diameter hole where the fan is mounted makes an ideal place for rf (and harmonic!) radiation to escape if it's not shielded. So, another letter to DenTron produced a fine-mesh fan grille, which also was sent out without charge.

There are two ways to mount the grille: I scraped the paint off *both* faces of the die-cast fan housing to ensure good electrical contact between the grille and fan housing and also from the fan housing to the chassis.

The alternate method is to place the fine-mesh grille against the chassis and mount the old fan with the protective grille on top of it. You can use four rubber grommets to shock-mount the fan, which cuts down on the noise, but be sure to seal around the edge so the fan is exhausting air from the chassis and not through the open space between the fan and chassis.

Using a GR Strobotac, I found the fan speed dropped only 20 rpm, indicating that air delivery was substantially unchanged. I also added ½″ to the rear feet of the amplifier to increase clearance from the shelf. Be sure you allow enough room behind the amplifier (distance from a wall, drapes, etc.) so airflow is not impeded.

So far, these problems were minor irritations. The real jolt came when a nearby ham came over and said, "You got spurs that jingle-jangle my new TS-120." He brought over an H-P spectrum analyzer he had borrowed from work (every ham shack should have one, if you have 10 kilobucks to spare!) and we hooked it up to my TS-820S/Clipperton-L combination.

Gadzooks! The screen looked like a Christmas tree—spurious emissions and harmonics all over! Well, first, the 820 did need neutralizing (my fault when installing new finals) and then the in-band emissions were gone. After this, we checked the TS-820 into a dummy load, and its harmonics were well below its −40-dB specs. But, when it drove the Clipperton, the harmonic output of the 820 went up. The answer is simple, my friends. The 820 wasn't seeing a 50-Ohm resistive load, but some complex impedance that exceeded its linear operating range.

Examination of the Clipperton's input circuit disclosed that it was untuned and had no swamping resistor. Taking readings of the vswr between the 820's *output* and the Clipperton's *input* showed the lowest vswr to be 1.65:1 and the highest to be over 3:1! (See Table 1.)

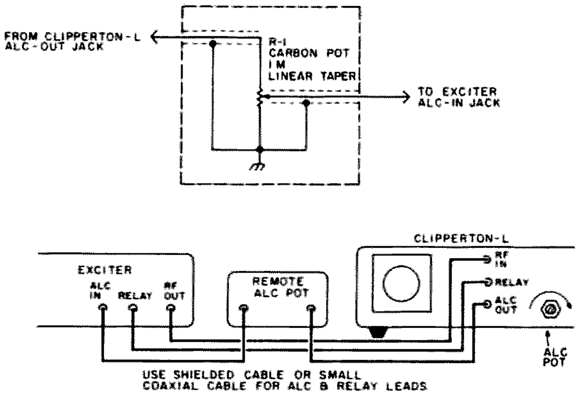


Fig. 1. Remote alc control arrangement.

No wonder that some of the solid-state-output rigs either won't drive the Clipperton or just shut down, depending on their design. By the way, the catalog specs the input at 1.5:1, average.

One solution is to put an antenna tuner between the exciter and the Clipperton—if you don't mind twiddling knobs. Another solution is to put in pi-networks for each band to match the exciter to the Clipperton, but there is no easy way to do this the way the unit is laid out.

The third solution is to buy the outboard attachment that DenTron sells as the CM-1 accessory. This contains pi-networks using toroidal inductors (which cannot be optimized for each band) and caps, as well as a relay to permit straight-through operation when operating barefoot. The CM-1 is touted as a "plug and play" unit, but you have to run a 12-volt lead through the fan lead hole in the Clipperton and solder it to the relay +12-volt lead inside. I found it easier to drill a hole near the internal relay, use RG-174/U, and run it to the CM-1 (be careful not to get metal chips inside!).

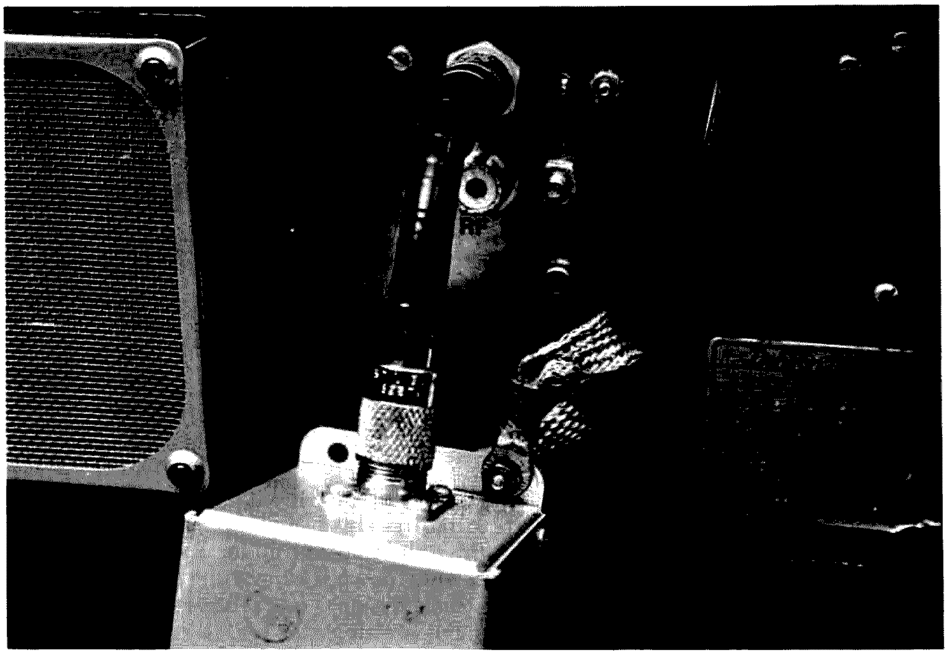
Examining two of the CM-1s showed that they did

Frequency (MHz)	Clipperton-L Power Output (Watts)	Input Vswr
29.0	650	1.75:1
21.225	680	1.65:1
14.20	600	1.97:1
7.15	550	2.15:1
3.75	350	3.11:1
1.90	500	2.56:1

Table 1. Output power of Clipperton into 50-Ohm dummy load without input matching. Alc setting is advanced such that output power of 700 Watts is reduced to 600 Watts.

Band	DenTron Data to FCC Power (Watts)		K4JW Measurements			
			Power (Watts)		Clipperton	CM-1 network
	P_{in}	P_{out}	P_{in}	P_{out}	input vswr	input vswr
160	882	390	1000	460	2.6:1	1.8:1
80	891	440	1000	675	3.1:1	1.5:1
40	819	520	1000	580	2.2:1	1.5:1
20	748	340	1000	600	2.0:1	1.5:1
15	614	340	1000	500	1.7:1	1.3:1
10	na	na	1000	400	2.0:1	2.0:1

Table 2. Type-acceptance data vs. author's measurements before and after input (vswr) matching; na = not applicable.



Low-pass filter with short RG-214 coax lead, ground-braid to chassis. Note the fine-wire mesh fan grille. Lead at upper right is RG-174 carrying 12 V dc for CM-1 relay.

not agree with the schematic supplied. One used a common network for 15 and 20 meters while the other used separate networks, although the one using a single coil seemed to do a good job.

Now for the alc pot located on the *back* of the Clipperton. Nothing in the operating manual mentions its adjustment, so, in response to another request to DenTron I was told to use either sine-wave or trapezoidal scope patterns and to set them for 100% modulation. Lacking a scope, you can adjust the alc pot to produce 1 kW input.

Alc is part of a control loop for the *system* of the exciter and linear; its setting should prevent the exciter from driving the amplifier into a non-linear condition which generates harmonics, spurs, etc. Now, I realize this poses a problem for the designer. If the amplifier is to be used with one particular exciter, he can select fixed values for the alc system (maybe!). But, when the amplifier is to be used with many different exciters, each having its own alc characteristics and voltage requirements, he has to employ an adjustable system. So, it becomes apparent that the alc adjustment pot should be accessible from the *front* of the amplifier. One of the popular amplifiers does have this facility, and its manufacturer tells you to set it on *each band*!

Without poking more holes in the Clipperton, this can be accomplished as shown in Fig. 1. A 1-megohm linear-taper carbon pot is mounted in a small chassis box. Shielded leads are used, one to the exciter, the other to the alc output jack on the Clipperon. Turn the Clipperton pot wide open (clockwise) and use the new alc pot to set the amplifier to 1 kW dc input on each band. This is about 0.580 Amps at 1700 V when in the "CW-X" position.

It is useful to put a scale labeled from 0 to 100 on the front of the box so you can log the approximate readings for each band. The alc pot can be mounted on the CM-1 accessory, or both can be mounted on the side of the Clipperton (don't cover up the screw used to hold the top cover on the amplifier).

Harmonics still plagued me. Why wasn't my good Drake TV-3300 LP filter working to specs? First, there is no easy way to mount it to the back panel of the Clipperton. Second, the 10" piece of old coax I was using between the filter and the Clipperton was leaking like a sieve!

I replaced this with a 4" length of RG-214, which is a silver-plated, double-shielded cable that can be used up into the gigahertz range. You can make a reasonable substitute by taking two lengths of RG-8/U, cutting the outer jacket off one piece and sliding the braid off the other piece. Slide this braid over the first piece of coax, making it a double-shielded cable. After the connectors are attached, cover the outside with PVC tape. Take another piece of RG-8/U and strip the shielding off to make a heavy grounding braid between the case of the low-pass filter and the chassis ground of the Clipperton.

What had been happening was that the shunt caps in the low-pass filter were grounded to its case, and I had a ground loop. Also, "sheet currents" were flowing over the surface of the poorly-grounded filter case allowing harmonics to pass on to the antenna. Now the Drake did the job it was supposed to—greater than −80dB at 40 MHz.

One day I lost bias—so I thought. The output waveform was distorted and the resting plate current was zero. Examination showed no contact through the relay used for transmit-receive. This relay has a 3PDT configuration, one set of contacts being used to switch the bias from cutoff (through R3, 47k) to operating bias (9.1 V from a 1N3308 zener). The contact was pitted. In order to burnish this and the other relay contacts, it is necessary to remove the relay spring, pull the armature back, and burnish all contact surfaces. Insulation barriers prevent inserting the burnishing tool while the relay is in place.

Some instability was noted after the Clipperton had been converted for 10-meter operation. By making sure the Load control on the Clipperton is set at *least* above "3" on 15 meters and above "5" on 10 meters, the instability usually will disappear.

Going around the Clipperton with an rf sniffer and using the spectrum analyzer connected to an antenna approximately 100 yards away, the results showed these fixes did the job. Incidentally, I use an SPC transmatch between the Clipperton/low-pass filter and the antennas, giving me more harmonic attenuation and aiding in the presentation of a 50-Ohm resistive load to the amplifier at the operating frequency.

I use a relay switching system on my tri-band quad, so the 10-meter section is not electrically connected to the feedline when operating 20 meters, thus further reducing the radiated second harmonic. (It's kind of embarrassing to be called on the land-line by a local and told that you are QRMing their 10-meter round table when you are operating on 20!)

Conclusions

1. Whether your exciter is solid-state or vacuum-tube output, use an antenna tuner or CM-1 pi-network between the exciter and the Clipperton.

2. Install a variable alc control pot where you can easily set it for each band.

3. Ground everything—the exciter, the Clipperton, the low-pass filter, transmatch, etc. Use braid as short as possible.

4. Throttle back on the audio gain; 1 kW input is *not* always necessary.

DenTron now has come out with a "new model" of the Clipperton-L. They have put the tuned networks in the input and inside the box. An extra section has been added to the band-selector switch which switches can-type relays mounted on a PC board they put on the left-side wall. These relays switch in the proper input pi-network.

It is understood that older units can be sent back to the factory for modification and/or a kit for field-modification will be available.

My thanks to Walt Kunde K5BVM for consultation and checking my tests, to Mike DeZego WA4RXC for instrumentation and help in running tests, and to W4TL, K4WB, and W4LQS for info on their Clippertons. ■

The Traveling Ham's Allband Antenna

—is this the ultimate portable system?

This antenna system was designed for travel. It can be assembled and put up by one man in less than 30 minutes, and it packs neatly in a Chevette. Despite the portability, it does an excellent job of radiating. A mast made up of five-foot steel sections supports a 10-meter beam. The guy wires are multiband inverted vees covering 80 through 10, with the traps located near the ends, making the radiating portions several half wavelengths on 20, 15, and 10. This results in some gain and in wide operating bandwidths on all of the bands.

The mast is almost 35 feet high. The five-foot sections of steel TV masting are strong but wobble a bit at the joints. (Aluminum tube of the same size is available but it is not strong enough.) By leaning the mast against two of its guy wires—see Photo B—one man can lift the mast and beam and add a section at the bottom. When raised to full height and the other two guys are tied, the base

Photo A. The portable antenna system has a 10-meter beam atop a pole made from short sections of TV mast, guyed by two inverted vees that give complete coverage, 80 through 10 meters.

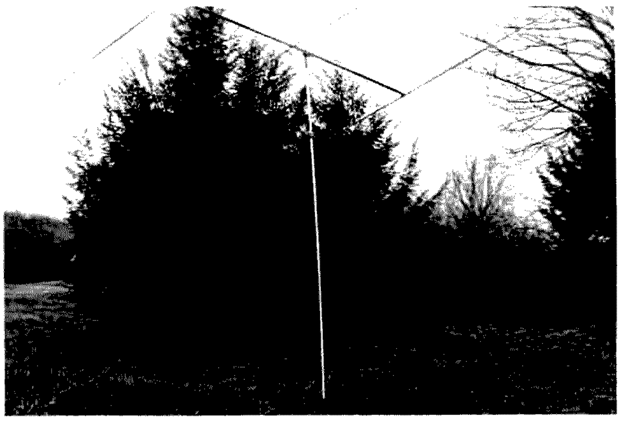

Photo B. By leaning the mast against two of its guys, one man can lift it from the bottom and insert another 5-foot section of the mast. The whole structure is light enough so that this is no problem.

	10m	15m
Reflector	17' 2"	23' 7"
Driven element	16' 6"	22' 4"
Director	15' 9"	21' 8"

Table 1. Element lengths for three-element beams based on driven-element-to-director spacing of 6' 4" and a driven-element-to-reflector spacing of 5' 6". From graphs in ARRL Antenna Book.

of the mast is moved under the top. An extra set of guy strings part way up will keep the mast straight and the beam level, but I don't usually bother.

The whole structure can be put on a rooftop if a fairly flat one is accessible and fewer mast sections are used. A chimney can be a base and so can a vent pipe of the drainage system. A U-bolt on the mast can be bent to hook on the pipe, as shown in Fig. 1.

The beam is the Radio Shack CB beam. Reduce the element lengths to those in Table 1. Notice that the boom length is adequate to make a three-element, 15-meter beam if that is preferred. The ends of the elements will accept 3/8" tubing extensions. The gamma match needs no modification on 10, and there is room enough to extend it to match a 15-meter driven element. If you buy a new CB beam, watch out for the assembly instructions; they have interchanged the reflector and director spacings.

The beam becomes quick-take-apart with a few simple changes during assembly. The boom joint can be loosened on one side only, and that half of the boom slid out of the joint. Each element-to-boom clamp is modified as shown in Fig. 2. One half of the element stays with the U-bolt and clamp and the other half slides out after the hose clamp is loosened. Cut off the end of this half-element right at the middle of the hole for the U-bolt, and don't use a bolt through the clamp and element as is done on the other side. During assembly, that half-element is pushed right up against the U-bolt as a stop, and then you know it is located correctly. The outer tube needs to be slotted under the hose clamp.

I color-coded the elements and boom to simplify layout of the parts on the ground before assembly. Red and green spray paint for the reflector and director are appropriate! Spray after the beam is assembled so that the paint doesn't interfere with electrical connections.

A short length of steel masting is attached to the boom joint. This is visible in Photo B. A tapered end of one of the mast sections is inserted in it to mount the beam on the mast. This leaves enough slip to rotate the beam around the mast. No rotor is used. I tied string to the ends of the boom and rotate it and secure it with the string. The mechanical and electrical complexity of a rotor in the system isn't warranted.

The two multiband vees are fed by the same 52-Ohm coaxial cable. Guy rings, one insulated from the mast by several layers of tape, support the center of the vees—see Fig. 3. Hose clamps under the rings prevent them from sliding down. A chassis coax connector was soldered to the lower galvanized ring with the inner conductor connection passing through one of the holes in the ring. A short wire connects this to the upper ring. The two halves on each vee are joined to these two rings so

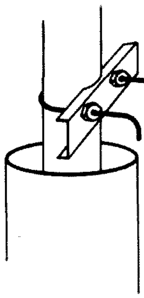

Fig. 1. A vent pipe makes a secure base for the antenna mast. With the U-bolt bent to hook on the edge, the pipe will support a short length of mast upright until the guys are tied.

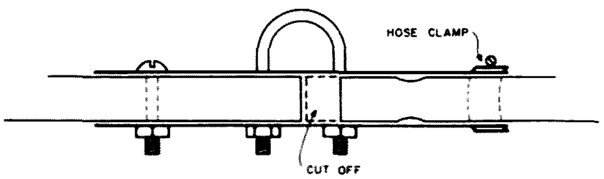

Fig. 2. The boom-to-element clamp modifications. The half-element on the right is held in place by the hose clamp. Its end has been cut off at the hole for the U-bolt. The U-bolt nuts are loosened to remove the element from the boom, and the hose clamp loosened to separate the two halves of the element.

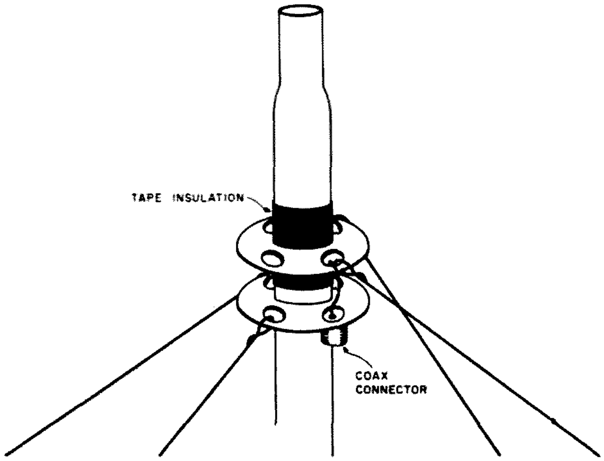

Fig. 3. Two guy rings are used to support the center of the inverted vees. The top one is insulated from the mast by electrical tape, and a hose clamp beneath it prevents it from slipping down. A chassis coax connector is soldered to the lower ring and its center conductor is connected to the upper ring.

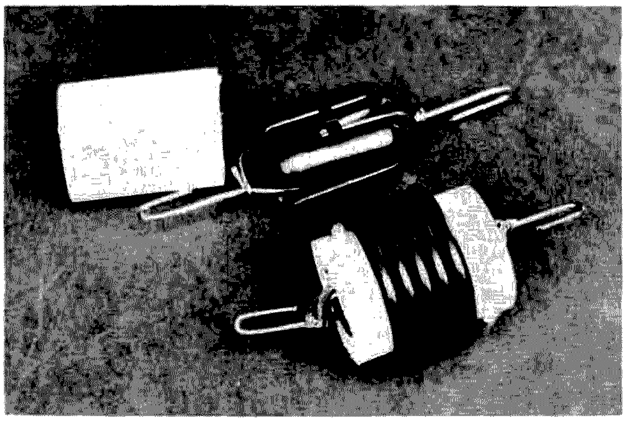

Photo C. One of the traps made from coaxial cable. The white polyethylene tube is a tight fit over the plastic egg insulator and serves as a coil form.

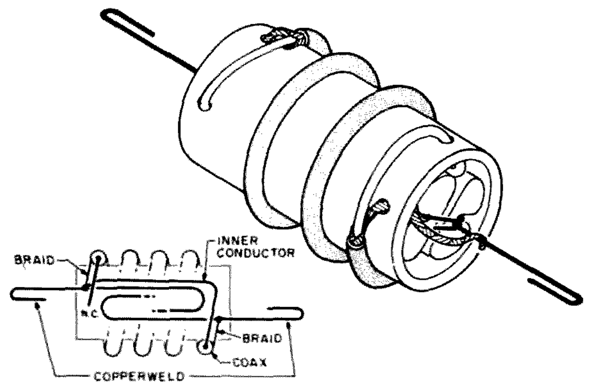

Fig. 4. Showing the connections so that a single length of coaxial cable becomes both coil and capacitor for a trap. The braid connects to the copperweld wire which will join the trap to the antenna. The inner conductor separates from the braid, passes through a hole 90° from the braid hole, and is routed through the egg insulator to be soldered to the braid and copperweld at the other end of the coil. The inner conductor at the upper end of the coil does not connect to anything. To hold it in place and insulate it, it is tucked into a shallow diagonal hole in the polyethylene coil form.

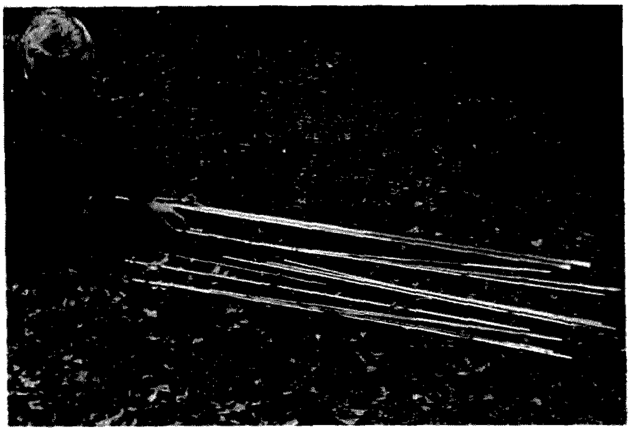

Photo D. There isn't much there after the beam and its boom are disassembled.

that the wires at one ring go off at right angles to each other. During travel, the guy rings and vees all stay connected to their mast section.

The vee for 40, 15, and 10 meters is a bit unusual. The 10-meter trap isolates three half waves in the middle and acts as a loading coil on 15 and 40. This is critical since harmonic antennas, such as a half wave on 7 MHz working as three half waves on 21 MHz, do not work out exactly. A half-wave dipole is too short to be three half waves on its third harmonic because of the lack of end capacity for the middle wavelength at the higher frequency. In this antenna, the loading coil effect of the 10-meter trap compensates for this; the trap is near a current loop for 15 meters and loads it more than it does 40 meters, bringing both bands into resonance with low swr on the same length of wire.

The long inverted vee works on 20 and 80 meters, with the traps cutting off three half waves on 14 MHz. The traps are near the ends of both vees, out of the high-current parts of the antennas, which makes for good radiating efficiency. Another advantage of this layout is the wide bandwidths on most of the bands. Many trap antennas have very narrow operating bandwidths because of the heavy loading.

Automotive primary wire was used for the vees. The stranded copper is flexible, coils nicely, and doesn't kink. It also has a thick vinyl insulation which is a help when the antenna must pass through trees or against buildings. Vacation sites are seldom ideal.

Photo C and Fig. 4 show the construction of the traps. Each trap is made from a length of RG-58 coaxial cable connected so that the braid is the coil and the capacitance between the inner conductor and the braid becomes the trap capacitor. In brief, the coax braid makes excellent trap coil with very high Q, and the distributed capacitance of the cable is a high voltage, stable capacitor. Notice the cross-connection of the inner conductor from the right end of the coil (Fig. 4) to connect to the left end of the coil. There would be no capacitor formed if it were simply joined to the outer braid at the right end of the coil.

The trap is built up on a plastic egg insulator and a two-inch length of 1½" polyethylene tubing as a coil form. This tubing, with a 1/8" thick wall, is a tight fit over the insulator and also helps to protect the free end of the inner conductor. This point, at the left end of the coil in Fig. 4, has high voltage with respect to surrounding parts of the trap and needs protection. Drill a diagonal hole into but not through the wall of the polyethylene and put that free end in it.

Start building a trap by forcing an egg into the polyethylene tube and attaching short lengths of wire, preferably copperweld, around the egg as is normally done with an antenna insulator. These wires inside the coil will have some capacity and so will be part of the trap circuit. Don't attach the antenna wire yet, since this adds extra capacity and prevents finding the correct trap resonant frequency. Remove about three inches of outer jacket from the end of the coax and push the braid back and loosen it. Work a hole in the braid, fold the cable, and feed the inner conductor and its insulation through the braid. The two are now separated as shown in Fig. 4.

The braid goes through a

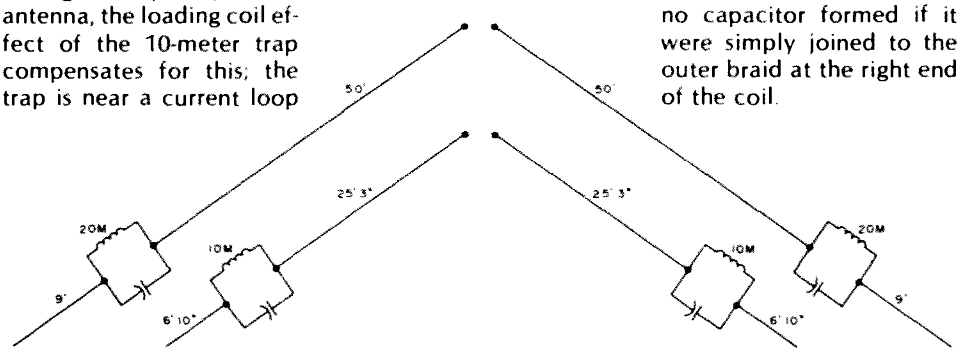

Fig. 5. Dimensions of the inverted vees. The long one is three half waves on 20 meters and a half wave on 80. The shorter one below is three half waves on 10 meters with the ten-meter trap slightly loading the entire length so that both 15 meters and 40 meters are resonant.

hole in the coil form and is soldered to the copperweld wire. the inner conductor goes through a hole a quarter turn away from the braid, passes through the egg beside the copperweld, and is soldered to it at the other end. Wind 3¾ turns of coax onto the polyethylene form for a 10-meter trap— 6¾ turns for a 20-meter trap. The holes should be drilled near the ends of the form so that the turns can be spaced out for tuning. A dip meter checked against a calibrated receiver is needed. Tune each trap for the middle of its band. After it is installed in the antenna, it will dip lower in frequency by about 1 MHz for the 10-meter trap and about .5 MHz for the 20-meter one.

All the electrical connections are soldered, and corrosion should not be a problem. The coils need to be secured in place after tuning, and the coax should have some weatherproofing so that water does not get inside. Silicone rubber is an excellent insulator. If it is in a tube, it is sticky and smelly as it comes out, but Dow-Corning sells a silicone rubber roofing material that will brush on. It comes only in quarts—about $7 in the discount stores. The trap could also simply be wrapped with electrical tape.

This antenna system has been up and down countless times in its development and tuning, and it also has been to the mountains and to the shore several times. It really is portable. The compromises (no rotor, wobbly mast, lightweight guys) are all mechanical; electrically it works very well.

Either the vees or the beam could be beefed up for a permanent installation, of course. Parts will function alone, too. I have not taken the beam to the shore where the houses are so close together. Also, if there isn't enough room to stretch out the 80-meter leg, I just use part of it as a guy wire and still have a good performer on 40, 15, and 10 from the other half. The tuning can be affected by nearby objects or the ends coming down close to the ground. It is best to tune it at home under conditions similar to those it will meet on vacation and accept the inevitable variations under field conditions.

Readers are encouraged to build the traps described here for their own use, but manufacturers are cautioned that a patent application has been filed on them and all rights under the Patent Code will be strictly enforced. ■

Photo E. *The beam can be disassembled and repacked in its original carton for travel. It extends up between the front seats of my subcompact.*

Note: A kit of parts to aid in making traps is available from R. H. Johns—Scientific Instruments, 3379 Papermill Road, Huntingdon Valley PA 19006, for $4.50 plus $1.00 postage. Each kit contains parts for four traps, egg insulators, polyethylene coil forms, and #14 copperweld wire. Coaxial cable, RG-58A/U, with stranded inner conductor to facilitate separating the inner and outer conductors from each other, is available at $.25 a foot. About 15 feet is needed for the four traps.

KIM's Magic Fingers

—RTTY transmit program

Author's Note: A substantial period of time has elapsed since the following program was first written. Since then, many things have elapsed. Although the following program is a working version, there have been many improvements in radioteletype algorithms for the 6502. Therefore, the article should be looked upon as a basis for the "first-time user" to get some ideas to start from. Some of the subroutines may be valuable in the creation of a sophisticated system.

There have been numerous articles on the KIM-1, and many of those available are right up the ham's alley. Among those offered have been CW receive and transmit programs and RTTY receive programs, but I have yet to see a RTTY transmit scheme published. For all you fellow KIM-1 owners who are RTTY fanatics, this article will be just what you are looking for.

The old mechanical monsters have their good points, e.g., hard copy, and the 28 is quieter than most others. The 28 ASR is even like a regular typewriter to the touch, but nothing is like an all-electronic keyboard. If you are among those who type faster than 60 wpm, then even the "ole 28" is a bit of a pain, especially when you go too fast, lock up the keyboard, and characters are missed in your frenzy.

Having had a KIM-1 for about six months along with an SWTP ASCII keyboard, I proceeded to arrange a method of transmitting 5-level Baudot with this combination. I had several standards which had to be met:

- No limitations on typing speed.
- Automatic case shift for FIGS and LTRS.
- Automatic CR/LF/LTRS on receipt of a CR from the keyboard or after 65 characters and the end of a line.
- No splitting up of a word at the end of a line.
- Practicality: a system that would not give more trouble than it saved.

This whole project was tackled in several steps. Initially, I had to come up with a good routine to convert the ASCII character into a Baudot character and send it serially out of one pin on the PIA. This was not too terribly difficult.

(I must give credit at this time to someone whose article provided me with many ideas. The January, 1977, issue of *73 Magazine* contained an article on using the KIM-1 as a CW keyboard. I used James Pollock WB2DFA's ideas for the interface of the ASCII keyboard and the usage of the 256-character buffer. Both of his schemes worked smoothly on the Baudot program.)

At this point, we are able to transmit Baudot and type as fast as we want, but still have to put in the case shift manually. This was the next thing tackled. Once solved, the end-of-line (EOL) sequence, along with the character counting and space detection for the auto EOL sequence, was added. Finally, the whole thing was starting to look up!

Being (admittedly) the proud type, I wanted my print to be somehow distinguishable from "ordinary" print. This was added in the EOL sequence and appears as a colon neatly down the left margin. That will make people say "Ah ha, there is

Address	Function
0000	Baudot character currently being output.
0001	Baudot character currently being output.
0002	ASL counter in actual output subroutine.
0003	Character counter (number of chracters in the line currently being written).
0004	Contains the original ASCII character received from the FIFO buffer.
0005	LTRS/FIGS flag position. This will be a 00_h when in lowercase (LTRS) and will be a 20_h when in uppercase (FIGS).
17BF	Contains the value of the FIFO pointer.

Look-up table.

one of them computer freaks," for sure!

We now will step through the various routines and see how this thing works. Have a look at Fig. 2. (This is from the article by Pollock and is presented here for those who might not have that issue of *73*.) Notice that the ASCII data is presented to KIM offset one place to the left. This is so that we have PA0 as our output pin. This "ASL" is made up for in the coding and is offset by an "LSR." Also, be sure the strobe on your keyboard is normally high, going low whenever data is available. This is required for compatibility with the NMI input on KIM.

Next, we look at Fig. 1, where we see all the buffers or temporary storage and flag locations involved in the program. Address 0000_h and 0001_h both will contain the Baudot value of the ASCII character that is to be transmitted. The reason for this will be explained later in the "Fetch" routine. Address 0002_h is the ASL counter. This ensures that we get the one start bit, five data bits, and our stop bits. Note that we are using 2 stop bits in this program, but this slows the rate so little that the extra coding could not be justified.

Address 0003_h is the counter that senses how far across the page we are. If we reach 65 characters, KIM will look for the next space and then put in the EOL routine. This assures us that we will not split up the last word on the line. Address 0004_h contains the ASCII equivalent of the Baudot character currently being processed for output. Address 0005_h is the Baudot case flag. If this contains 00_h, we are currently in lowercase Baudot. If this is 20_h, we are in uppercase Baudot. Address $17BF_h$ is the value of the FIFO pointer. If this location is not equal to the value of the Y register, another character will be fetched from the FIFO buffer and be transmitted. So on it goes until it catches up to the Y register.

You will find the entry point at the standard 0200_h. Here, the parallel interface is programmed as inputs and output, corresponding to what we require. The vital places are initialized at 00_h, and the NMI vector at $17FA_h/17FB_h$ is set to point to the interrupt routine. From here, the program jumps to the FIFO fetch routine where it will look at the pointer to see if there is something to transmit (see explanation of address 17BF). If the output routine has caught up to the input rate, the KIM will transmit "diddles" which are composed of LTRS functions. This may be deleted by changing address $02D4_h$ to FB_h.

Now a word about the interrupt routine. This simply looks at the keyboard inputs when an NMI is received and stores the ASCII character in the buffer at location 0300_h plus the value of the Y register; it then increments the Y register to point to the next empty spot.

We will now look at the output routine. It boils down to the fact that whatever is in address 0001_h is chosen so that when it is shifted to the left, each bit which is shifted into the carry position will correspond to the Baudot code. Take the code for the letter "A". In ASCII, this is 41. So, when an "A" is typed on the keyboard, it will enter a 41 into the buffer (after LSR to preserve identity). This 41 is used as an index for the look-up table and is transferred to the X register. The accumulator is loaded with the contents of address 000_h + X, which will be 41. The look-up table shows us that address 0000_h plus 41_h (0041_h) is the place for the letter A. Here the accumulator is loaded with the value 63_h. This is then stored at addresses 0000_h and 0001_h.

Then the accumulator is reloaded with the original ASCII value—in this case, 41_h. If it is a space code, the LTRS/FIGS detection and shift is avoided because every time a space code would be received, the machine would be shifted to uppercase. A look at an ASCII code table will show you why. Next, it is checked for a CR code. If it is pres-

ent, the KIM will jump to the EOL routine, send out the CR/LF/FIGS/:/LTRS/SPACE codes, and set the line counter to 00_h and the case flag to LTRS. If none of the above has happened, then the character is checked for its case, i.e., upper or lower. If it is the same case as the previous character, the case shift routines are skipped, the character is output, and the program returns to the FIFO fetch routine. If the case is different, location 0005_h is checked to see what the last character's case was.

If it was LTRS case, and since we have already established it is a different case from the current character, we will jump to a FIGS load routine, which will be output. Here is where the purpose of storing the Baudot-encoded byte in two locations comes into play. After transmitting the FIGS command, we then have to transmit that uppercase character. Since 0001_h has been destroyed, the contents of 0000 is transferred to 0001 and then the shifted character is put out.

The EOL sequence is very simple. Each part of the EOL is consecutively loaded into 0001, and then we just JSR OUTPUT. When the EOL is finished, the counters are reinitiated at 00_h, the case flag is set to LTRS, and the contents of 000_h is transferred to 0001_h.

The output subroutine is actually very simple, also. Let's look at our ASCII "A". When this was looked up, the value of 63_h was stored at 0001_h. This 63_h breaks down to binary 01100011. Looking from left to right, we will always see a 0_2, and the last two on the right will always be 11_2. This corresponds to our one start bit and our two stop bits. The five in between will correspond to our Baudot code desired. A look at a Baudot code table shows us that "A" (Baudot) is actually 11000. Each time function is set for 22 ms, which occurs immediately before we set the output pin high or low, corresponding to the 1 or 0 of the carry position after the ASL. If 0002_h, our ASL counter, is minus, the character has been fully transmitted and the KIM checks how far it is along the line. If it has reached 65 characters and the current ASCII character being transmitted is a space, it will jump to the EOL routine. If not, it will just jump back from whence the JSR occurred.

Now you can see how easy it is to get your KIM doing wonderful things on RTTY. I have used this basic output routine in a great many things. One of the neatest ones was linking it to Tiny BASIC. This was a great addition to Tiny because it gave me a hard copy of the program, etc., but, boy, did it slow things down!

I hope this article has helped out those who would like to have their KIMs on RTTY but did not have the time to write the program, or whatever. It was a great educational experience for me, and a great deal of enjoyment was derived. KIM-1 has to be one of the best little rigs for this type of application, and many, many things can come to my mind when I start thinking about them.

Give me a call on 14.082500, for I am always on that frequency, autostart. You will find many other fellas with computers on that "computer autostart net." You will be amazed at some of the things happening in this field. ■

AX-190 Upgrade

—Collins components can make the difference

A few months ago, I completed modifications to my AX-190 as suggested in 73 Magazine.[1] This made a great improvement in the front-end response of the receiver and, although I decided to stop with the additions in the first part of the article and leave out the preamp, signals that were hard to hear on 10 meters are now S9. I highly recommend this easy modification.

There is another area where the AX-190 falls short of being a good amateur receiver, however, and that is in the area of selectivity. The AX-190 in stock form shares its circuit with the SX-190, which is a shortwave listening receiver offering good performance on AM but rather poor selectivity for use on crowded ham bands. The receiver second i-f operates at 455 kHz and utilizes two transformer-filters with a rated bandpass of 4.1 kHz at 6 dB down. After thinking about outboard filters and even of building a passive audio bandpass filter into the speaker box, I finally decided to go the proper route and install a Collins mechanical filter in the i-f circuit. The price of new filters of this type is rather high, and if you are on a budget such as mine, I advise shopping for one that is surplus.

After looking over the schematic[2] and then opening up the receiver, I made the happy discovery that the second mixer (Q8) is mounted on the vfo board and is, of course, enclosed by the vfo box. Its output is fed to the input of the i-f board by a shielded cable soldered to pin 13. This point is an ideal place in which to insert a filter. Also, as I looked at the bottom of the receiver, I noted that the vfo enclosure edges are extended to the bottom of the chassis, forming a perfectly located shielded box with ready-made holes for connections. This means that a new circuit board can be inserted into the existing circuit with excellent isolation and no modifications to existing boards.

Before any work starts, it would be advisable to tune the calibrator signal in at a high frequency and peak all controls for maximum. If the S-meter reading is noted, the crystal calibrator then can be used to adjust the circuit on the new filter board for unity gain after installation. Capacitors C4 and C5 are adjusted for a peak, and then R2 is adjusted until the same S-meter reading is obtained.

The filter used is a surplus Collins 455-FA-21 with a bandpass of 2.1 kHz and it is mounted on an etched circuit board along with resonating capacitors and an amplifier using an MPF102. This board is etched with a

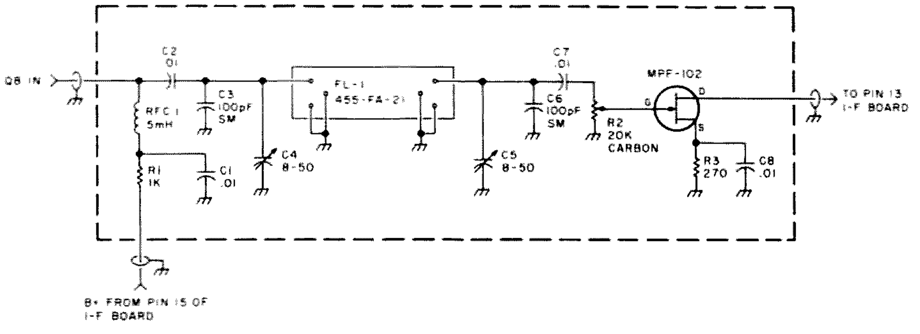

Fig. 1. A Collins filter for the AX-190. All connections to the circuit board are by shielded wire. See text for R2 adjustment. R2 is a surplus 10-turn, 20k carbon trimmer. R1, R2, and R3 are ¼ Watt.

maximum amount of ground plane remaining to provide isolation. I also added a shield on the foil side of the board between the input and output of the filter. The shield is simply a piece of circuit board material about ½-inch wide running the width of the board and attached with solder. I'm not sure it's necessary, but it is easy to do and certainly won't hurt.

The original shielded cable coming from Q8 to the i-f board is unsoldered from pin 13 and rerouted to the filter board which is mounted on the bottom panel of the vfo box. It may be necessary to splice on a small piece of cable, depending on how you mount the board. On the new board, the mixer product is coupled to the mechanical filter through a 0.01-uF ceramic capacitor (C2). A 100-pF silver mica capacitor (C3) with a paralleled 8-50-pF ceramic trimmer (C4) are used to resonate the input of the filter. The output of the filter is treated in the same way with C5 and C6 and is then fed to the gate of the MPF102 through a 0.01-uF ceramic (C7) and a miniature 20k ten-turn carbon pot. The output of the new filter is now simply a matter of attaching the drain of the MPF102 directly to pin 13 on the i-f board by a shielded cable. This also supplies B+ to the MPF102 as it did originally to Q8.

Of course, by this process Q8 no longer has B+, and this is restored by running another shielded cable from the power supply bus on the i-f board (pin 15) through a capacitor-resistor decoupling network on the new filter board. Just to be sure, I threw in an additional 5-mH choke. These components are labeled R1, C1, and RFC1 on the diagram, Fig. 1.

These modifications have resulted in a very satisfying receiver as far as SSB and CW are concerned, and comparisons with other highly-rated receivers are favorable. AM reception is no longer possible, but I'll accept that loss in the light of better performance in the other modes.

Many thanks are due to Dave Carlson VE7AQE who provided the circuit and the technical advice along with enough verbal abuse to get me going on this project! ■

Extra Accuracy for Heathkit Clocks

—a synchronous solution

Many amateurs have bought Heathkit® digital clocks for their stations. The clock kits are easy to build, can be wired for Zulu (GMT) time, and are a necessary piece of equipment for amateurs who participate in traffic nets or MARS operations.

Older models of the digital clocks were six-digit versions displaying hours, minutes, and seconds. Later versions are four-digit types which normally display only hours and minutes. These can be set to WWV time, after a fashion, by advancing the clock to the next minute, stopping the clock, and releasing it on the minute signal.

A much more accurate method of setting the model GS-1107 clock is to modify the clock for a seconds display. This allows the clock to be set exactly with the WWV signal. The seconds display is handy also for timing. The modification is relatively simple, consisting of cutting a trace on the PC board, wiring in a jumper wire, and replacing the snooze switch. An additional switch can be added to give a seconds display if the snooze feature must be retained. A similar modification can be done to any digital clock using the National MM5316 clock chip.

Perform the following modifications:

1. Cut the printed-circuit trace to pin 24, IC1 (clock IC) (see Fig. 1).
2. Add a strap from pin 32, IC1 to the PC trace previously connected to pin 24 (see Fig. 1).
3. Replace the spring-return snooze slide switch with a regular one-pole/two-position switch (Radio Shack 275-430). Wire the new switch the same as

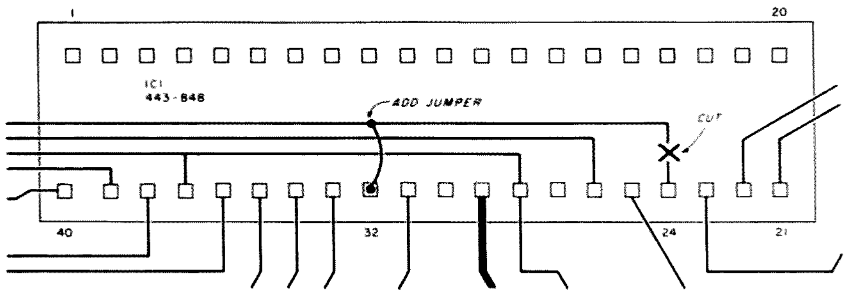

Fig. 1. Clock IC—printed circuit side.

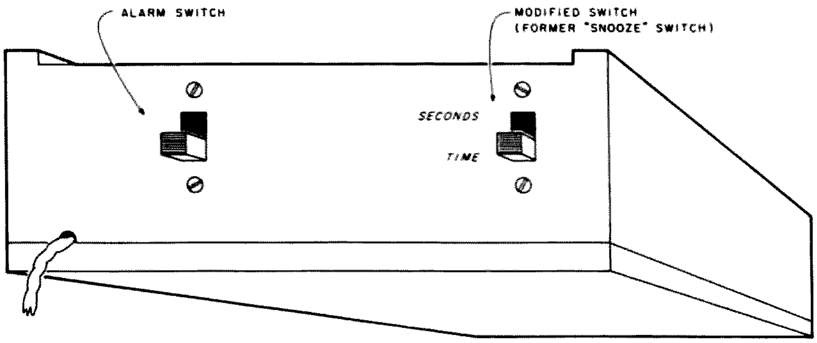

Fig. 2. GC-1107 clock—rear view.

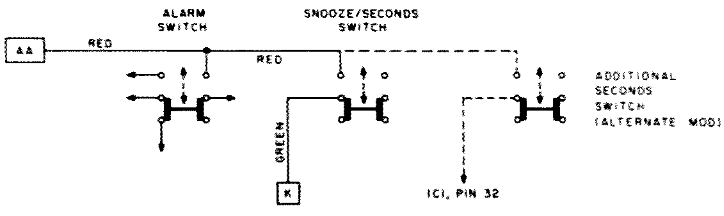

Fig. 3. Clock switch wiring.

the original switch (see Fig. 3).

● Snooze switch will now provide two displays:

a) "Time" display: normal 24-hour format.

b) "Seconds" display: digit 4 = blanked, digit 3 = minutes (units), digit 2 = 10s of seconds, digit 1 = seconds.

● When used in "seconds" display mode:

a) Slow switch: Will inhibit 60-cps input to the clock IC and prevent time from advancing.

b) Fast switch: Will reset seconds to zero without changing the minutes count.

c) Both switches at once: Will reset time to 12:00:00 am in 12-hour format; to 00:00:00 in 24-hour format.

● To set the clock to synchronize with WWV:

a) With former snooze switch in "time" display mode, set clock to current time plus one minute.

b) Switch to "seconds" display.

c) Depress fast switch (resets to X:00), release fast switch, and immediately depress slow switch (stops clock and holds time).

d) Upon receipt of the WWV tone (on the minute), release the slow switch.

e) Verify that the display changes from X:59 to Y:00 at the next WWV tone pulse (on the minute).

f) Set former snooze switch to "time" display mode.

If an additional switch is added for the "seconds" function, connect the center contact of the switch to pin 32 of IC1 (clock chip). Connect the normally-open contact of the switch to the wire which is common to the snooze and alarm switches (+22 V from power supply terminals AA, AB, AD, and AG)—see Fig. 3.■

The 160 Winners!

—W8LRL and W4CN take top honors

Bill Gosney KE7C
2665 Busby Road
Oak Harbor WA 98277

"The biggest and best ever held"—those were the words uttered by nearly everyone who participated in the 1981 160-Meter Phone Contest sponsored by *73*. Most contestants expressed their surprise at the enormous turnout of active stations on the bands. Many old-timers indicated it was the first time in their lives they've seen so many phone-band operators on 160 at one time! They weren't joking, either; the statistics tallied after the contest showed nearly 1,000 stations participated in the weekend extravaganza. Look at the results compared to last year for example:

	Entries	Participants
1980	74	569
1981	117	917
% Increase	58.1%	61.2%

Greater scores were witnessed, bigger signals were apparent, certainly more stations were on the air than ever before, and the propagation seemed to favor most everyone's fancy. I said "most," fellas! As well-known top-band operator Paul Engle K9QLL stated, "Last year's winner wouldn't have even made honorable mention this year!" If you weren't there to see it for yourself, let us tell you, the competition was extremely fierce. The contest results pretty well sum it up.

Wally Eckles W8LRL from West Virginia took first-place honors in the single-operator category with a remarkable score of 383,625 points. Of particular interest is the fact that the DX countries worked by Wally made the difference in the outcome of the event. Wally's fifteen-country total could not be matched by the nine countries of second-place finisher and well-known HF contest station KØRF. Though KØRF had the most QSOs in the contest (804), nearly twice that of last year's winner, the three multiplier credits earned for each DX country worked allowed W8LRL to pull out into the lead when the final scores were tabulated.

John Vaughn and company (AC4A, WD4ARQ, N4DUH, KA4DWX, KA4FJJ, WD4OSN, WA4QWJ, NF4R, K4TXJ, KD4U, and N4XM), representing the Amateur Radio Transmitting Society, Inc., of Louisville, Ken-

ZF2DX in Grand Cayman Island operated by KØGVB and WAØDXZ (wearing glasses). KØGVB was 2nd in the world last year.

CONTEST FEEDBACK

"This was my first 160 contest; in fact, at contest time I had only been on 160 meters about two weeks total. Had a really super time and you can be sure I will be back next year with bigger and better things."—K1LPS.

"The 160 contest again turned out to be a great success! Congrats on a job well done. The new rules worked out just fine and I wouldn't change a thing for next year. My biggest thrill was working W1BB, W2FJ, and W2EQS all the same weekend. I guess there is a first for everything?"—WA9EYY.

"Thanks for a most enjoyable contest and thanks to everyone for the contacts. I had to miss most of the first night and half of the second. I am already looking forward to next year's event."—KC8P.

"Suggest you make the contest mixed SSB/CW."—AA1K.

"No W5s or W7s; where were they? A great contest, though."—K1NBN.

"Competition is getting heavier (and much, much louder). I guess it is time for a new antenna system. The band opened up nicely Sunday morning. Thanks for a fun contest."—WB1HIH.

"The word got out about the best 160-meter contest and I wish I could have worked the thousands of stations I could hear. Hope we have the entire 160-meter band next year and we can spread out a little."—K2DWI.

"All set for the contest, then 2 days before I got the flu. I was left with little energy. My coughing kept tripping the VOX. See everyone in the 3rd annual event, I am sure."—K3IXD.

"Found the conditions here on the east coast good to zero-land; not much heard to 5-, 6-, or 7-land, however; did hear HP3, KP2, and a VK6 at about 0100Z on the 18th. Certainly looking forward to next year."—K2SJB.

"Biggest thrills were working Hawaii and Nova Scotia answering my CQ."—W5LKP.

"Lots of fun and good turnout for the 2nd annual event. Only wish the DX conditions were better for some of us."—W3BGN.

"This is my very first 160-meter contest and only my second contest of any kind. I enjoyed it very much. I wish time would have allowed me to work longer."—K4ZGA.

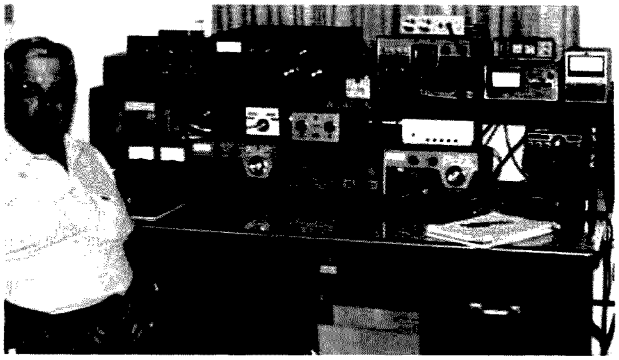
"Contest rules as of now make no incentive to work more than one DX station in each country. I feel the rules should give extra points for each DX station worked."—W4PZV.

"Good contest! Unfortunately, I could only operate one night."—AE6U.

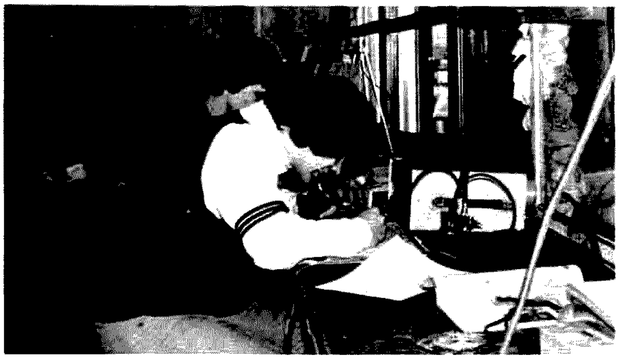
"Hadn't been on 160 since 1954 until the weekend of the contest. I strung up a new antenna and jumped in with both feet (until the rig blew up Friday night). This put me out of action until the following evening. I had a ball anyway! See you next year for sure."—N4ARO.

"Forty minutes late starting due to finishing the beverage antenna in the moonlight. It helped me work two European countries, however."—N4IN.

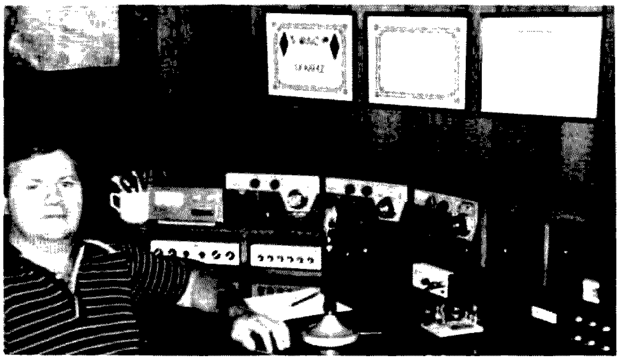
"My first 160-meter contest. Not a good score, but wanted to show my support. Enjoyed it nonetheless. Hope to improve



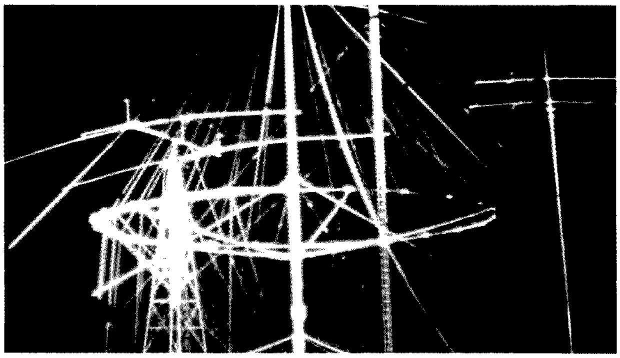
WD4OSN pictured here at his station after all the dust cleared. This station took top multi honors under the call W4CN.



KA9F manned by WD9IHI in the foreground and station owner Neil in the back as they operate from the high school press box high above the football stadium where dipoles are strung across the field.



W8LRL, overall 160-meter champion! An unbelievable score of 383,625 points, 775 QSOs, 47 states, 7 provinces, and 15 DX countries on single sideband. Need we say more about this popular contester, "Mr. Gentleman" of the "Gentleman's Band."



N7DF, top 7-land station for the second year in a row. Look at the spider-web. Could this be why?

my antenna system to be more competitive. Thanks to 73 Magazine for the sponsorship. See you again next year."—W5SOD.

"As always, it was again proven that 160 is the 'Gentleman's Band.' My thanks to the fellows who really tried to get me through to the east coast, even though I didn't make it (sob!)."—W6WBY.

"Lots of bug signals and weak ears. Big and little guns calling the coast to no avail! All in all, it was lots of fun. Sunday participation dropped off drastically it seemed."—KK6C.

"Heard many stations that couldn't hear me—HP1XRK, AH6BK, KC4OV, etc. My noise level was 59+. A fun contest, though, and there sure was a noticeable lot of activity."—AK7F.

"Never heard so much activity on 160 before! Worked more states in 4 hours than in the rest of my not-too-active 22 years. Used a 330-foot AM broadcast tower after sign-off. Having a 5/8-wave vertical sure was nice (hi). Next year we may even match the impedance."—K8EXF.

"Never has 160 sounded so continuous QRM."—W8IM.

"Sure was fun. Only wish I could have worked the second night."—K8CFU.

"Had a lot more fun than last year. Did a little better also (hi). Missed some prime time operating hours due to company. Sure looking forward to next year, though."—W8QBF.

"Really enjoyed the contest. A lot more activity than I expected to find. The event seems to be a great success. Thanks to 73 Magazine!"—W8LRL.

"Where were Wyoming and New Mexico? Missed several other multipliers, too. Enjoyed the contest again this year. Seemed to be much more activity and I was at least able to beat last year's score in spite of the limited operating time."—N9GT.

"Conditions were excellent. Local competition was very, very stiff!"—WBØCMM.

"Again I enjoyed the contest. Conditions were less favorable, though. Higher noise, weaker propagation. Pleased to note the higher turnout, especially VEs. Acquired 1 more state and 3 more provinces thanks to the contest."—VE4WR.

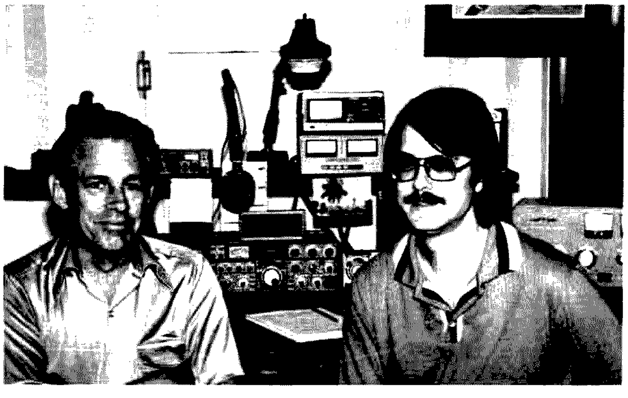
"Back to the drawing boards for the 160 antenna. I heard at least 25 stations from the US calling me, but they didn't hear my return signal evidently. Planning a sloper for future 160 work. Couldn't hear W1-land at all."—HP1XRK.

"This was my first effort in a contest since I got my license last April. I really had fun. Wish my antennas were a few feet higher (hi). All in all, had a great time."—VE1BWW.

"This was quite a contest. Last year's score would hardly be an honorable mention this year. Murphy got me and I missed some of the best hours of the contest due to a blown switchbox and preamp. Never heard so many signals on 160 before. There must have been over 1,000 stations on there! Sure hope the test continues every year!"—K9QLL.

"Wish I had submitted my records last year. I enjoyed the contest a great deal. One of the best, I think! Certainly more contesters this year. Hopefully, it will grow in popularity while not challenging in simplicity and good operators. It was zero degrees or less and had about 16" of snow. Made my new 160 antenna plans impossible."—N8AKY.

WA9EYY achieved 2nd highest multi-op score in the world assisted by K9ZDN.



Multi-op station WDØBNC was top zero-land station and third in the world. WDØBNC (left) and WAØTKJ (right).

W3YOZ preparing for the big event. Photo represents only one of three verticals mounted in the river with extensive radial systems. This station was 5th in the world and high scorer in the 3rd call district.

tucky, had a clear-cut victory in the multi-operator category with a score of 226,525 points. This team was followed by second-place finisher WA9EYY and his multi-operator assistant K9ZDN with 193,475 points. Unlike the race in the single-operator category, the difference in this heat was obviously the QSO count. A margin of 152 QSOs separated the first- and second-place stations, while the second-place station led in provinces and countries worked.

This year's multi-op effort was a surprise to us all. We hope this success will be incentive enough for more stations to come out of the woodwork, join the fun, and challenge the competition on 160!

John Summach VE3MFA from Burlington, Ontario, Canada, was high scorer for all of Canada with 444 QSOs and 142,080 points. Leading the single-operator category for DX stations was C6ADV with 171 QSOs and 49,590 points. ZF2DX and multi-op crew KØGVB and WAØDXZ led in their category for DX stations with 241 contacts and 73,505 points total.

Evidently propagation to North America was not in the Europeans' favor, as DF2LM and SP5IXI both reported making contacts only within the Eastern Hemisphere. We're as optimistic as they are, however; they'll be back next year to try again as conditions *will* improve, won't they?

Sorting through all the statistics by computer, we found KØRF leading the pack with the most QSOs (804), followed by W8LRL with 775 stations worked. Other entries with 300 or more contacts included: W4CN (697); WBØCMM (676); W9RE (592); W3YOZ (580); WA9EYY (545); WDØBNC (513); AA1K (488); WDØBRD (485); N4KG (483); KC8P (457); VE3MFA (444);

W9ZX (439); W8VX (424); N7DF (412); K9QLL (406); WAØAVL/9 (399); KA9F (375); W8GIO (366); WB7FDQ (347); K6SE (344); AE6U (336); N9GT (330); AE5H (329); W9UP (325); KAØY (323); KB8AC (321); W4PZV (309); K9ZUH (300).

Our only disappointment (other than a disqualification which was made) was the representation from some of the Canadian provinces. With the rules changed to their favor from last year, we were expecting a greater turnout in this part of the continent. Out of a maximum of twelve provinces and territories possible, only nine were ever heard on the band, eight of which were logged by the three zero-land stations—KØRF, WBØCMM, and WDØBRD.

Speaking of multipliers, all fifty (50) states were heard on the band at one time or another. Yes, contrary to the belief of some east coasters, Hawaii was on there in full force (why no entries, though, fellas?), as was the state of Alaska. Of course, for the sake of the contest, Hawaii and Alaska counted as DX multipliers!

For the most states worked, KØRF's call pops up again, leading all other contestants with 48 states worked—a clean sweep! Others recording forty (40) or more states were: W4CN, W9LRL, WAØAVL/9, K9QLL, WDØBRD, WDØBNC, WBØCMM (47); N4KG, K6SE, WA9EYY, W9RE, KAØY (46); W3YOZ, N4CQ, N4IN, KB8AC, KC8P (45); AE5H, W8VX, K9ZUH, W9UP, W9ZX (44); AA1K, WB7FDQ, N9GT, VE3FMA (43); AE3T, W4VKK, N4UU, W4PZV, W5LKP, AE6U, N7DF, N8AKY, WD9GGY, KA9F (42); W3DHM, W4WWQ, K7VIC, K9BG (41); and ZF2DF (40).

With fifteen (15) countries to his credit, W8LRL was clearly the DX king as

well as being the overall winner of the contest. Other DX accomplishments with 5 or more countries: AA1K and W4PZV (11 countries total); DF2LM (10); N4IN, KØRF (9); VE1BNN, W3YOZ, N4KG, W5LKP, W9RE (8); C6ADV, HP1XRX, WBØCMM (7); W3DHM, N4UU, N4CQ, KB8AC, KA9F, WA9EYY ZF2DX (6); W3BGN, W4VKK, W4WWQ, K6SE, W8VX, W9UP, K9QLL, WDØBRD, WDØBNC, VE3MFA (5). An additional 33 entries managed to verify four or less countries each.

This year 21 countries were represented during the contest, another great surprise we never expected. Contestants logged such countries as San Andreas, Grand Cayman Islands, Bahamas, Puerto Rico, Bermuda, Panama, Dominican Republic, Netherlands Antilles, Venezuela, Hawaii, Alaska, England, Isle of Man, Northern Ireland, Netherlands, Australia, West Germany, Poland, Mexico, Peru, and, of course, the United States and Canada. All we need to do now is convince these top-band DX stations to join us again next year and hopefully this time we can talk them all into submitting an entry. Just think, each of them could have won an award to hang on the wall and boast about!

Table 2. Equipment used in the 160-Meter Phone Contest.

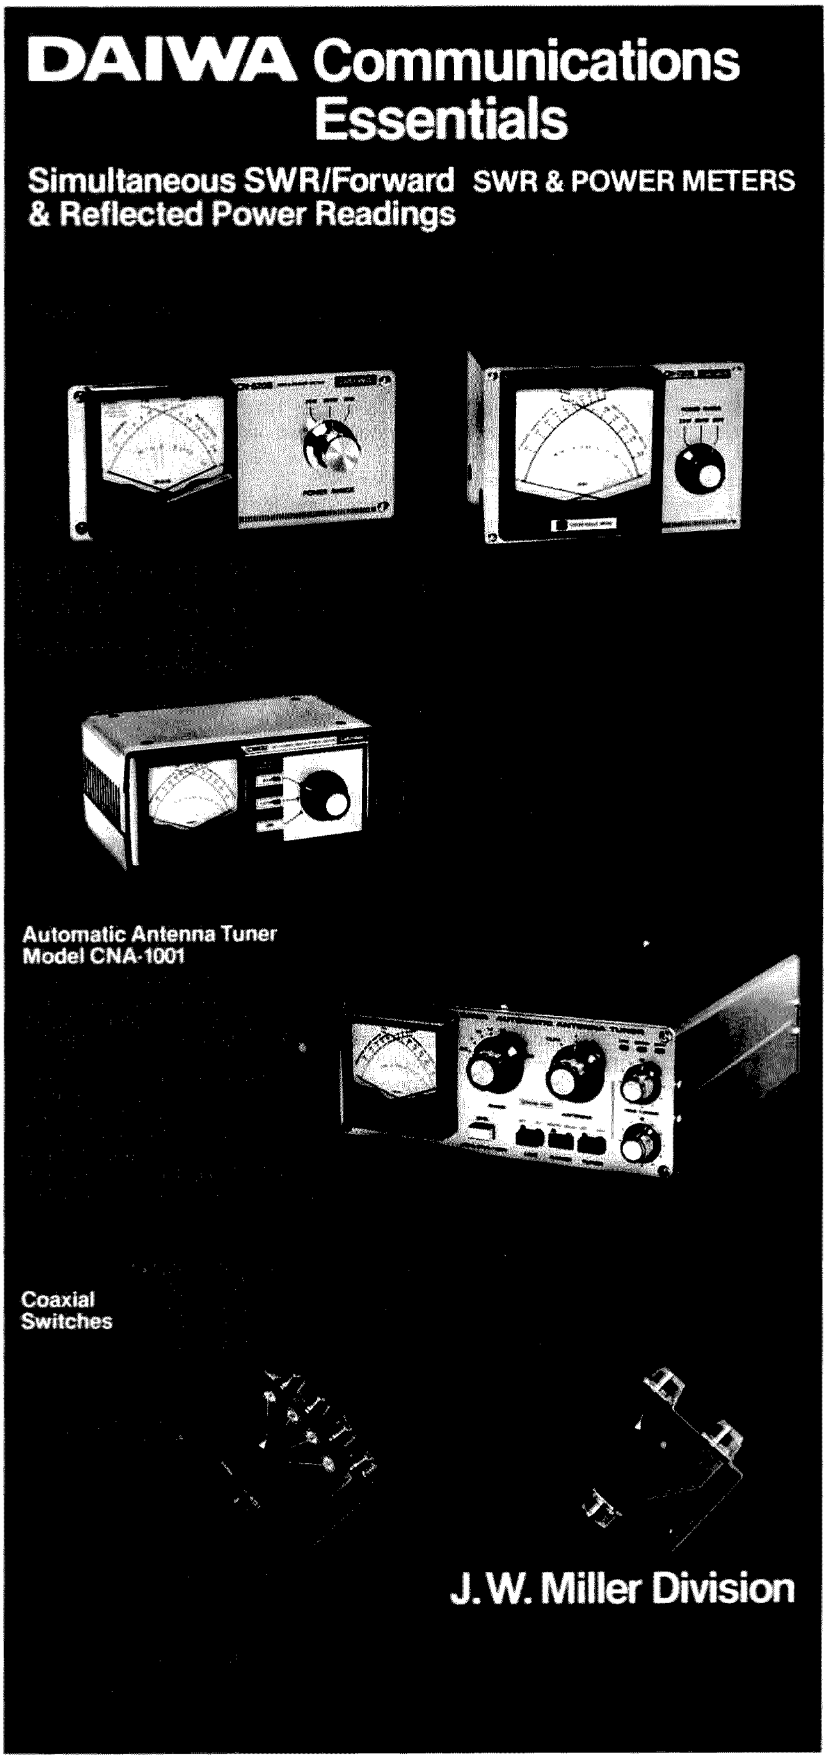
W9ZX was among the top five multi-op stations. Achieved 439 contacts and 120,725 points with the dedicated assistance of W9MWK.

over and everyone has submitted his entry, one of the most interesting parts of the contest committee's job is to tally all the equipment and antennas used by the contestants. We get the biggest kick out of the lame duck excuses some people will use for not getting on 160—for years hams have been saying it required too much real estate or it required a special home-brew rig of some fashion. Well, for the second year in a row, we have the results to prove all that is a bunch of hogwash. Look at the stats for yourself. Most of the antennas you see listed in Table 1 were erected on small city lots.

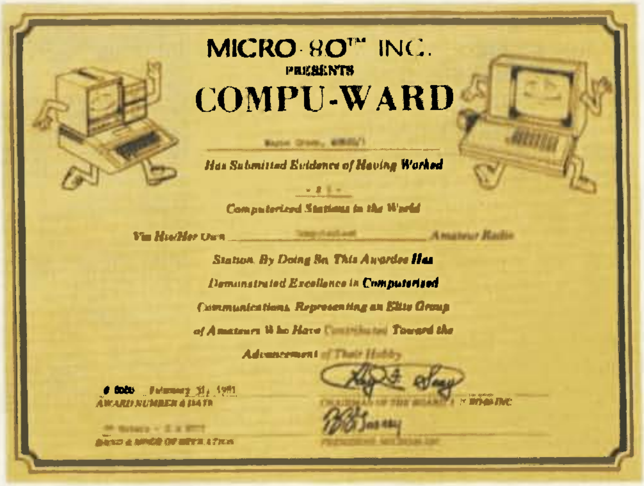
Now take a look at the equipment in Table 2. It's an old wives' tale; I don't see a home-brew rig in the bunch (I take that back—a modified Heathkit HW-12A).

It's been a great contest; we have Dan WA2CZB and Ed K3IXD, both members of our contest committee, to thank for that. This dedicated pair has been with the contest from the very start. Both were instrumental in assisting me back in early 1979 when we burnt the midnight oil trying to establish the rules for the event we've all experienced here. Both have agreed to be with us again next year for the third annual event, which I must remind you is just around the corner.

Help us pass the word for our next big event in January! Will W8LRL win again? Will KØRF take it all or will W7RM, W7WA, and W2PV come out of the woodwork and surprise us all? We hope that whatever happens, it will be a fun time for us all as the FCC has just announced the relaxation of rules governing 160 operation. Who knows, we may see DXCC in a weekend before it is all over! I'll be pruning and tuning; how 'bout you? ■



AWARDS



Bill Gosney KE7C
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

FREE OPERATING AWARD

Not many things in life are free these days. Boy, isn't that the truth! The expense of administering an awards program is no exception. The sponsor of this next award, however, is about to change all that.

Read the rules very carefully. All amateurs are eligible and can easily qualify with the station they now have! Though the awards program focuses on computer operation in the amateur bands, the applicant *does not* have to own a computer to qualify! Confused?

The sponsor recognizes the fact not all amateurs own a microcomputer (recent surveys indicate only 20% do). All of us have been exposed to one on the air several times the past couple years, probably without even knowing it. The emphasis of this award, therefore, is to work other stations who are computerized, whether your station is or not.

Still confused? Perhaps the rules of the award program will clarify any areas of uncertainty.

As publicized in over 25 individual amateur radio publications throughout the world, the COMPU-WARD is sponsored by Micro-80 Incorporated (all employees are licensed amateurs). COMPU-WARD is available *free* to all licensed amateurs and shortwave listeners thoughout the world. Emphasis of this award is focused on the advancement of both the amateur radio and computer hobbies through demonstrated excellence in the art of computerized communications.

Stations applying for the COMPU-WARD *may or may not have* a computerized station of his or her own; however, it must be emphasized that all stations contacted *must* be computerized! The *contacted station* must have his transmitter interfaced with a computer such as a TRS-80, Apple, Pet, Heathkit, Atari, etc.

You might ask how to know if the stations are computerized or not. The first answer is obvious—ask! More routinely, however, you will be able to easily identify a computerized transmission. The CW sent will be absolutely flawless—perfect weighting of the characters and everything. The only thing that may throw you will be memory keyers. Most generally a station will mention the fact that he or she is computerized when he tells you the equipment he is using. On RTTY, the copy will be just like a newspaper column, most of the time with justified margins and lines.

To be valid, all contacts must be made on or after January 1, 1980. Two awards are being offered *free*: (1) HF Bands—29.7 MHz and below; (2) VHF/UHF—50.0 MHz and above.

All contacts must be made on one or any combination of the following modes (including any modes authorized by the FCC since the release of this announcement): RTTY, CW, SSTV, and ASCII. Crossmode communications will not be recognized for this award program.

Single-band and mixed-band endorsements will be given in each band segment (HF, VHF, UHF, etc.). Cross-band operation will only be accepted for OSCAR contacts. OSCAR contacts will be recognized as a VHF/UHF accomplishment even though some downlink signals are heard on 10 meters. Contacts through repeaters are also acceptable.

To qualify for either COMPU-WARD: Applicants *with* a computerized station of his or her own must contact a minimum of 15 other computerized stations; applicants *without* a computerized station of his or her own must contact a minimum of 25 computerized stations.

To apply for COMPU-WARD, prepare a list of contacts in prefix order. List each call worked, mode utilized, frequency or band of operation, and state whether you do or do not have a computer which you used to make these contacts. *Do not send QSL cards*! Have your list of contacts verified by a local amateur or radio club official.

Forward your list of contacts along with a large self-addressed stamped envelope (3½" × 9") to the following address. Foreign stations must provide 2 IRCs to substitute the need for a stamp for overseas mailing: COMPU-WARD Program, 2665 North Busby Road, Oak Harbor WA 98277.

QRP AMATEUR RADIO CLUB INTERNATIONAL, INC.: A HISTORY AND ITS AWARDS PROGRAM

QRP Amateur Radio Club International, Inc., was founded in 1961 by K6JSS as an organization for the growing segment of amateurs which enjoys the challenge of running low power.

The club's principle of helping reduce interference on crowded bands is reflected in its motto: Power is no substitute for skill. QRP ARCI's power limits are 50 Watts output on CW and 100 Watts PEP output on sideband, although its officially recognized definition of low-power operation is the internationally used five Watts output on CW and ten Watts output PEP on sideband. The club does not advocate the reduction of power limits authorized by any nation, however.

QRP ARCI has a comprehensive awards program, holds informal monthly QSO parties the first Sunday, sponsors two formal QSO parties (one in the spring and one each fall), sponsors weekly national and regional phone and CW nets, joins with other QRP groups in activities, and publishes *QRP Quarterly*, a newsletter rich in technical articles and news of QRP-related events and activities.

73 MAGAZINE AWARDS PROGRAM

Ten-Meter DX Decade Award

9 WB8LSV — 10 WB9WFZ — 11 W8AKS/6

DX Capitals of the World

12 WA2SRM
13 WA2YEX
14 DF7QD
15 VK6YL
16 OE8MOK
17 8P6OV

Specialty Communications DX Award

1 W2ODA (RTTY)
2 WB0QCD (SSTV)
3 WB7BFK (RTTY)
4 WB0QCD (RTTY)
5 WD9GRI (RTTY)
6 WB6CDM (RTTY)
7 N3AKO (RTTY)
8 DU1EFZ (RTTY)

District Endurance Award
(Times In Minutes)

1 AJ8L (50)
2 WL7ACY (55)
3 WB6CDM/7 (12)
4 WA3PMI/7 (36)
5 WA4ZLZ (54)
6 GI4KCE (8.3)
7 WA2MCE (54)

Additional information on the extensive awards program can be had by sending a large SASE to: Doug Crittendon WB1ESN, 33 Taylor Street, Pittsfield MA 01201.

Full information on club membership, which is available to domestic and foreign amateurs at a moderate, one-time initiation fee and an even more reasonable annual renewal thereafter, can be had by sending an SASE to the secretary-treasurer, Edwin R. Lappi WD4LOO, 203 Lynn Drive, Carrboro NC 27510.

Traditional QRP frequencies are: CW—1810, 3560, 7040, 14060, 21060, 28060, 50360; phone—1810, 3985, 7285, 14385, 21385, 28885, 50385; Novice—3710, 7110, 21110, 28110.

QRP Amateur Radio Club International officers as of April 15, 1981, were as follows: Thomas W. Davis K8IF, President, 11729 Merriman Road, Livonia MI 48150; Robert L. Jenks K7ZVA, Vice President, 11714 Masonic Road, Tacoma WA 98498; Edwin R. Lappi WD4LOO, Secretary-Treasurer, 203 Lynn Drive, Carrboro NC 27510; Frederick W. Bonavita W5QJM, Publicity, Box 12072, Capital Station, Austin TX 78711; William Dickerson WA2JOC, Contest Chair, 352 Crampton Drive, Monroe MI 48161; Doug Crittenden WB1ESN, Awards Chair, 33 Taylor Street, Pittsfield MA 01201; Peter N. Spotts N1ABS, Editor, *QRP Quarterly*, 140 Warren Street, Needham MA 02192; Richard A. Crowell W4WQW, Legal Officer, 803 Oak Plaza Road, Kingston TN 37763.

QRP Amateur Radio Club International has revamped its awards program to reflect internationally recognized low-power levels and has named a new awards manager and secretary-treasurer.

"We are going to can all 100-Watt awards," said Thom Davis K8IF, president of the club which celebrates its 20th anniversary this year.

With one exception, QRP ARCI's board of directors has approved changes effective June 1, 1981, requiring awards to be based on a power *output* of not more than five Watts CW or ten Watts PEP on sideband. The organization previously offered awards with an optional power limit of up to 100 Watts input for CW or 200 Watts PEP for sideband.

The restructuring is in keeping with the club's main objective of showing how the use of limited power permits maximum enjoyment of amateur radio, minimizes interference on crowded bands, and offers operators a genuine challenge. As QRP ARCI's motto says: "Power is no substitute for skill."

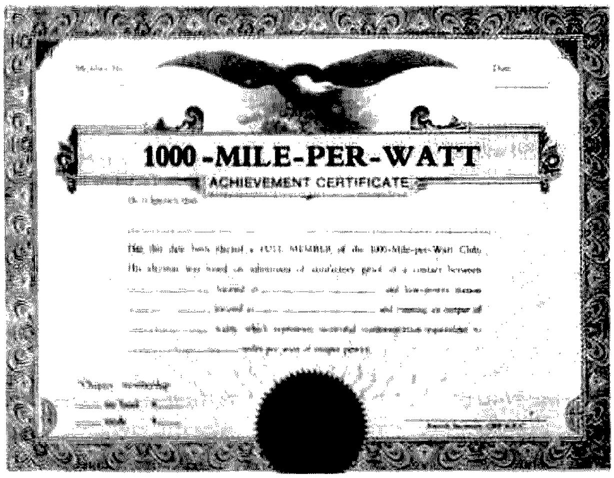
Leading QRP ARCI's awards is the popular KW/M Award, or the thousand-miles-per-Watt certificate, as it is known. It is available to any amateur transmitting from or receiving the signals of a low-power station such that the Great Circle distance between the two ends, when divided by the power output, equals or exceeds 1,000 miles per Watt. Additional certificates may be earned on different bands and with different modes.

DXCC-QRP, as its name implies, is awarded to any amateur station for confirmed contacts with stations in 100 of the ARRL's approved countries. QRP-WAS is available to any amateur for confirmed contacts in each of the 50 United States, and QRP-WAC goes to any amateur for confirmed contacts with a station in each of the six continents.

For each of the above awards, the following rules apply:

1) Power *output* may not exceed five Watts CW or ten Watts PEP on sideband.

2) Since members' QRP numbers are not made available by the club, it will accept as proof for any club award a QSO with a club member giving his/her QRP number and power level in the log data. Otherwise, a QSL card



is needed for confirmation. Copies of cards or a General Certificate Rule list are acceptable.

3) Special endorsement seals are available on awards for which power output on both ends of the contact was within the QRP limits set forth in #1 above.

4) An all-one-band or -mode (AOBM) endorsement also is available on request and if supported by log data, QSLs, or GCR list.

5) All awards are endorsed for power used and whether "one-way" or "two-way."

6) Under the General Certificate Rule, award sponsors will accept as proof of confirmed contacts and that claimed QSLs are on hand if the list is (a) signed by a radio club official, (b) signed by two amateur radio operators of General class or higher, or (c) signed by the applicant with his/her signature notarized and attesting that the QSLs are as claimed. If QSLs are sent as proof and are to be returned, they must be accompanied by sufficient postage.

The only club award to be "grandfathered" in during the restructuring of the program is the QRP-25 Award. It is issued to any amateur who works 25 QRP ARCI members, and endorsements are available for 50, 100, 200, and so on in multiples of 100. Associate members must have been running 50 Watts output or less on CW (or 100 Watts PEP on SSB) to qualify.

To apply for any of the club's awards, send copies of log data, QSLs, or a GCR list plus power and mode used by all stations together with two dollars or ten IRCs to the new awards chairman: Doug Crittenden WB1ESN, 33 Taylor Street, Pittsfield MA 01201.

QRP ARCI's secretary-treasurer, who has additional information on membership, is Edwin R. Lappi WD4LOO, 203 Lynn Drive, Carrboro NC 27510.

For additional information, the club's public relations officer is: Fred Bonavita W5QJM, PO Box 12072, Capital Station, Austin TX 78711.

LAKE SHORE ARA AWARDS

The Lake Shore Amateur Radio Association has informed us of two very unique awards being made available through their organization. Let's look at both the Lake Erie and the Pennsylvania series awards respectively.

The Lake Erie Award

This award is issued for working counties bordering the shores of Lake Erie. There are thirteen (13) counties involved in the four (4) states of New York, Pennsylvania, Ohio, and Michigan. They are Monroe and Wayne counties in Michigan, Chautauqua and Erie counties in New York, Erie county in Pennsylvania, and Ashtabula, Lake, Cuyahoga, Lorian, Erie, Sandusky, Ottawa, and Lucas counties in the state of Ohio.

Amateurs in either of the above four states must work all four states and 10 of the 13 counties to be eligible for this award. The rest of the US, and including those stations within Canada, must work 6 of the 13 counties in only 3 of the 4 represented states.

There is no starting time nor are there any endorsements for this awards program. SWL stations may also apply for this award on a heard basis.

Send no QSL cards; merely have your list of contacts verified by at least a couple amateurs and forward it with an awards fee of $1.00 in US funds or 5 IRCs. Mail your application to: David Maynard WA3EZN, 304 Barker Street, Girard PA 16417.

The Pennsylvania Award Series

The Pennsylvania Award is a series of five awards being offered by the Lake Shore Amateur Radio Association:

The Pennsylvania Cities Award is issued for working 10 cities in Pennsylvania. Of course the cities must be those which are the largest: Philadelphia, Pittsburgh, Erie, Scranton, Allentown, Reading, Harrisburg, Bethlehem, Altoona, and Chester. DX stations need only work 8 of the cities and may substitute Wilkes-Barre, Lancaster, York, and Johnstown.

The VHF Award requires six (6) contacts with any Pennsylvania station on six meters and above. Pennsylvania stations must work 25 stations in 15 counties. The rest of the US and Canada must work 20 stations in 10 counties, while DX stations must work at least 10 stations in 5 counties.

The Novice Award requires amateurs of the state to work a minimum of 25 other Novices in 15 counties; the balance of the US and Canada must work 20 Novices in 10 counties and DX stations must work 10 Novices in 15 counties.

The YL Award requires 25 Pennsylvania YLs be worked in 15 counties for those living in Pennsylvania. All others in the US and Canada must work 20 YLs in 10 counties, while all DX stations, including Alaska and Hawaii, must work a minimum of 10 YLs in Pennsylvania in a minimum of 5 Pennsylvania counties.

The Mobile Award requires those amateurs in Pennsylvania to work a minimum of 25 fellow Pennsylvania mobiles in 15 counties. The balance of the US

and Canada must work 20 mobile stations in 10 counties, while DX stations have to work only 10 mobile stations in 5 counties.

There are no endorsements issued for any of the five Pennsylvania series awards. There is no time limit. To qualify for the award, have your list of contacts verified by at least two amateurs and forward it to the awards manager along with an award fee for each award in the amount of $1.00 to defray cost of administering the program. Mail your applications to: David Maynard WA3EZN, 304 Barker Street, Girard PA 16417.

PEARL HARBOR STATION

The Pearl Harbor Submarine Base Amateur Radio Station, KH6SP, will operate the weekend of 4 December 1981 in recognition of the fortieth anniversary of the Japanese attack on Pearl Harbor on 7 December 1941. Operation will be on twenty and fifteen meters SSB approximately 20 kHz inside the General phone band and on CW about 40 kHz up from the band edge. A certificate QSL will be provided for amateur contacts and an SWL certificate for SWL reports. QSL to KH6SP or KH6BD, the station custodian.

SPECIAL EVENTS STATION PLANNED AT PLIMOTH PLANTATION, THANKSGIVING DAY

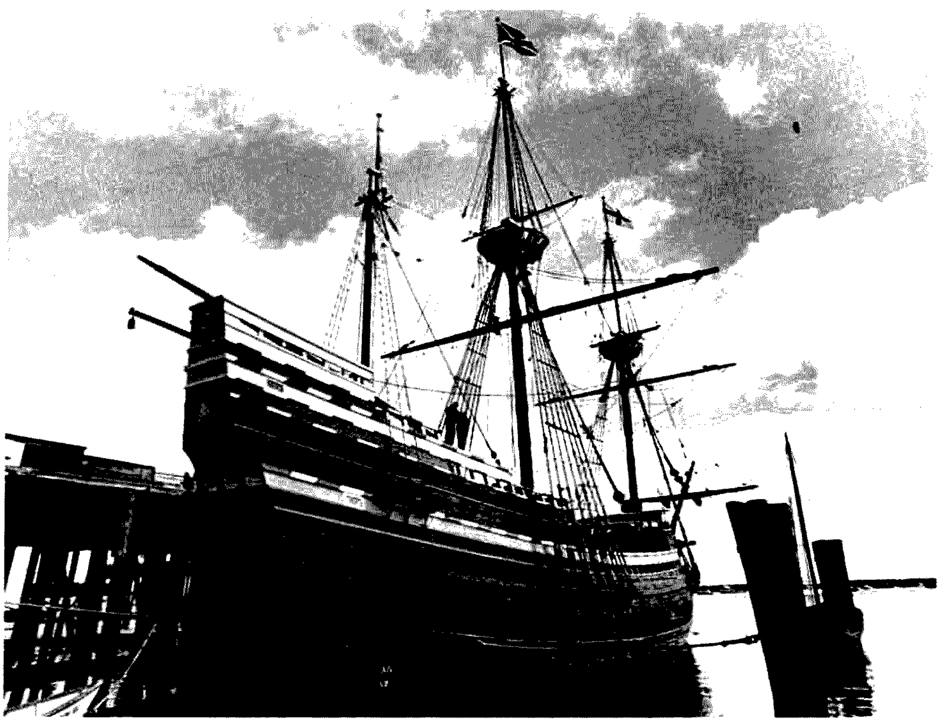
A special events station from Plymouth, Massachusetts (America's Hometown) will be sponsored by the Whitman Amateur Radio Club and Plimoth Plantation on Thanksgiving Day, November 26, 1981.

An attractive certificate suitable for framing will be issued to any (foreign or domestic) amateur who makes contact with this station, which will operate from 9:00 am until 3:00 pm. Depending on weather conditions, members of the Whitman club will operate the station from a dockside location near *Mayflower II* on the Plymouth waterfront, or from an indoor site near the museum's 1627 Pilgrim Village.

Plimoth Plantation is an unusual living history museum which depicts life in 17th century Plimoth Colony. Its sites include the 1627 Pilgrim Village and Wampanoag Summer Settlement, and *Mayflower II*, a replica of the type of ship that brought the Pilgrims to the New World in 1620.The Whitman Amateur Radio Club was established in 1965. Club officers hope the Thanksgiving Day special events station will become a regular part of the community's holiday celebration.

To receive a certificate, send proof of contact and a large (9 × 12) self-addressed stamped envelope or $1.00 to Whitman Amateur Radio Club, Box 48, Whitman MA 02382. Hours for this event will be 1400 to 2000 UTC. Frequencies to be used: 1400 to 1500 UTC, 21.260 (England only); 1500 to 1700 UTC, 7.280 ± QRM; 1700 to 2000 UTC, 21.385 ± QRM.

For additional information, contact Ed Hommel KA1CZS, Whitman Amateur Radio Club, Box 48, Whitman MA 02382 or Rosemary Carrol, Plimoth Plantation, Box 1620, Plymouth MA 02360, (617)-746-1622.



The Mayflower II.

SUBMARINE EXPEDITION

The Choctaw/Muskogee Amateur Radio Clubs are planning an expedition to the submarine *USS Batfish*. Using the callsign W5FX, they will operate on November 13 from 8 to 12 pm and November 14 from 8 am to 4 pm. CW operation will take place 22 kHz above the Extra class band on 80, 40, 20, and 15 meters. Phone frequencies are 3805, 7168, 14230, and 21268 kHz. Send an SASE to Calvin G. Ladd W5FX, 109 E. Myrtle Dr., Midwest City OK 73110, for a QSL card.

RADIO VATICANA AWARD

The Radio Vaticana on the occasion of the 50th anniversary of its foundation issues an award available to licensed amateurs anywhere in the world under the following rules:

Contacts with stations in the Vatican State must be made during the period starting from October 1, 1981 on any amateur band from 315 MHz to 144 MHz and any mode (AM, SSB, CW, RTTY) including cross-band relay and mixed. This period ends on February 1, 1982.

Stations in Europe (including the USSR in the European territory) and the USA (except Alaska and Hawaii) must work (or listen to) at least 2 different stations operating from the Vatican State. At present there are only three licensed stations: HV1CN, HV2VO, and HV3SJ.

Stations outside the above-mentioned countries must work (or hear) at least one HV station.

The applicant must prove the required contact(s) by sending a photocopy of the QSLs received from the HV stations during this period.

The application must be sent before December 31, 1983. This must be addressed with the above-mentioned documents to: Radio Vaticana HV1CN, Citta Del Vaticana, Europa.

FUN!

ANTENNAS

Antennas have always been a sore spot with me. I mean, you probably think that someone who writes a monthly column for *73* has some sort of fancy array on 10, 15, and 20, and nothing less than full rhombics for 40 and 80. Not quite.

My DX antenna is a TA-33 Jr. with a reflector element that refuses to remain horizontal. I should fix it, but three families (two of the bird variety, one spider) would suddenly be rendered nestless. Foreclosing on somebody's home is not my forte.

My 40-80 meter antenna system is even funnier. Actually, it's a system in the truest sense of the word. You see, it starts in the front of my attic, runs through the house to the back attic window, across my backyard where it swings around an abandoned telephone pole, traverses the backyard once again, and terminates along the eaves of my fair abode. On the air, I call it a "doublet," since the lead-in joins this contrivance somewhere near the middle of its journey, but "unusual" may be a more apt description. As far as the radiation pattern goes, let's just say that on a good day I can actually hear stations on eastern Long Island. Once, I even got a 57 from a guy in Hicksville.

From time to time, whenever I say or write something a particular person finds objectionable, he'll threaten to "pin" my coax. "Fine business," I say, "A dead short may just improve my signal." Faced with this unexpected reaction, I'm usually left unmolested.

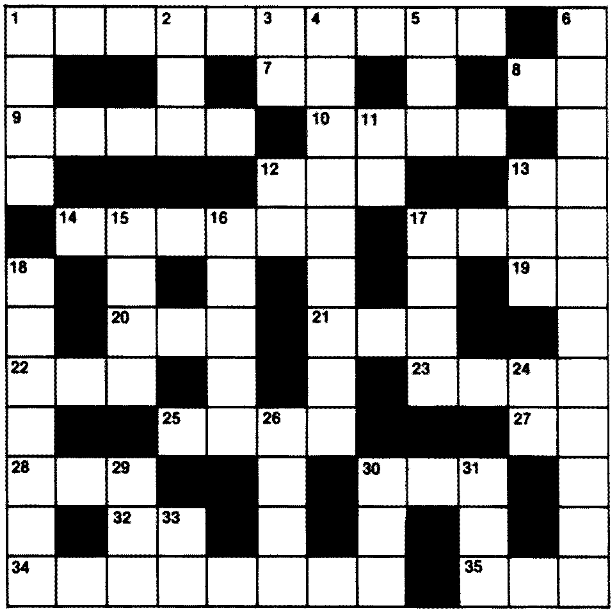

Illustration 1.

ELEMENT 1—CROSSWORD PUZZLE
(Illustration 1)

Across

1) Often confused with long-wire (2 words)
7) Russian "yes"
8) TV villain
9) Amplification plural
10) Antenna perpendicular to horizon (abbr.)
12) Old professional organization (abbr.)
13) A junction
14) Antenna cylinder system
17) Splices
19) Ham appellation (abbr.)
20) Antenna deterioration
21) Morse question mark
22) Dah's partner
23) Signal attenuation along feedline
25) Movable switch part
27) America (abbr.)
28) Some regard antennas as a work of this
30) 540-1600 kHz (abbr.)
32) 14 across measurement
34) Tower and mast
35) Big ______

Down

1) HT and mobile
2) Great noise
3) WA3AJR's sheepskin
4) SHF feed
5) Received (abbr.)
6) ______ line
11) Professional person (abbr.)
12) Opposite of out
13) Oscillator type (abbr.)
15) RTTY circuit (abbr.)
16) A preliminary treatise (abbr.)
17) Many mobile whips use a loading one
18) Antenna spokes
24) Egypt prefix
26) A ham's den
29) 160 meters: ______ band
30) Connection point
31) 80-meter rhombic, for instance
33) Differential of power (abbr.)

ELEMENT 2—ALPHABET GAME

Complete the nine words below by placing letters of the alphabet on every dash. Use each letter only once. The letter "K" is not used.

A B C D E F G H I J K L M
N O P Q R S T U V W X Y Z

1) _ A _ E _
2) _ P _ L E
3) A _ R A _
4) _ U A _
5) _ A _ _ N
6) _ E _ P
7) _ _ T C _
8) H E L _ _
9) R E _ L _ _ _ O R
10) _ R O U _ D

ELEMENT 3—SCRAMBLED WORDS

Unscramble these words associated with antennas.

dictroer
pictrosoi
rotwe
moob
loarabap
bleca
gaiy
nidmow
gainpsc
zolatipanori

ELEMENT 4—MATCHING

Match the definition to the antenna.

Column A

1) Voltage-fed Hertz antenna using a two-wire tuned feeder attached to one end of the radiator.
2) Directional antenna made up of several parallel tubes or wires. One element is a driven radiator, another a parasitic reflector, and the remaining element(s) are parasitic directors.
3) Omnidirectional antenna consisting of a metal disk attached to a metal cone.
4) Diamond-shaped, non-resonant antenna with directional characteristics. Uses a non-inductive resistor at its far end.

5) Center-fed single wire that's one-half the operating wavelength.
6) An elongated cone-like antenna, composed of parallel elements attached to cylindrical supports, center-fed.
7) Broad-spectrum antenna with element spacing and lengths that increase logarithmically from one antenna end to the other.
8) Large number of vertical radiators fixed in a plane.
9) A number of connected parallel wires arranged around a circular spreader.
10) Antenna composed of a coil wound around an element.

Column B

A) Discone
B) Sausage
C) Log indent
D) Zepp
E) Cage
F) Ferrite rod
G) Yagi or beam
H) Beverage
I) Curtain
J) Log periodic
K) Dipole

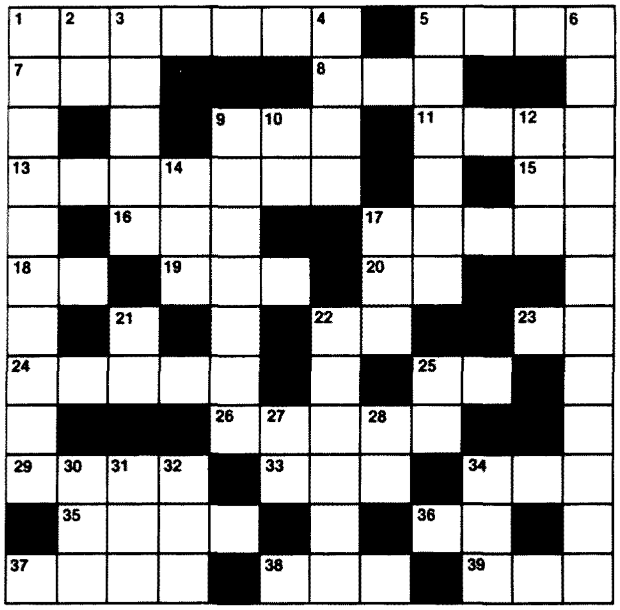

Illustration 2.

ELEMENT 5—CRYPTIC CROSSWORD (Illustration 2)

Think our usual monthly crossword is too easy? Try this one on for size. We call it a cryptic crossword because of the clues we give you: very vague, extremely ambiguous. Think you can handle it? Well, you better have a superb background in antennas, ham radio, electronics, and life.

Across

1) 3-D antenna
2) Slashing skyhook
3) Angry old society (abbr.)
8) Alphabet: 15, 14, and 9
9) OSCAR farewell (abbr.)
11) Zilch
13) Join
15) UA assent
16) TA-33's junior
17) Antenna soar
18) Extended λ
19) Don Ameche's unit
20) Metal-oxide, reverse (abbr.)
22) SW-BC system (abbr.)
23) Barry's locale (abbr.)
24) Detection and ranging
25) Bangkok beginning
26) Pardon
29) Antenna inventor
33) Struck
34) Lotsa (abbr.)
35) The DX hunt
36) Burning trap description
37) Straight up skyhook
38) Fundamental beam substance (abbr.)
39) Here

Down

1) Radius vector-ly
2) Relating to U on CW
3) Antenna glows
4) Fail
5) Off-center antenna
6) Line direction
9) Shoes
10) Antenna position to tower
12) Hello? Hello? (abbr.)
14) Up and down baker
17) Hiram (abbr.)
21) Mast girth (abbr.)
22) Topic synonym
25) Before brid
27) Finnish exclamation
28) Wireless speech (abbr.)
30) Golden
31) Air-to-air missile (abbr.)
32) Alphabet: 10 minus 1, 13, and 13 plus 7
34) Top skip

THE ANSWERS

Element 1:
See Illustration 1A.

Element 2:
1—WAVES, 2—JPOLE, 3—ARRAY, 4—QUAD, 5—BALUN, 6—ZEPP, 7—MATCH, 8—HELIX, 9—REFLECTOR, 10—GROUND.

Element 3:
(Reading from left to right) director, boom, windom; isotropic, parabola, spacing; tower, cable, polarization; yagi.

Element 4:
1—D, 2—G, 3—A, 4—H, 5—K, 6—E, 7—J, 8—I, 9—B, 10—F

Element 5:
See Illustration 2A.

SCORING

Element 1:
Twenty points for the completed puzzle, or ½ point for each question correctly answered.

Element 2:
Two points for each word.

Element 3:
Two points for each word unscrambled.

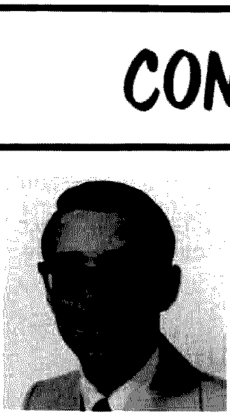
Element 4:
Two points for each definition matched to the correct antenna.

Element 5:
Twenty points for the completed puzzle, or ½ point for each question correctly answered.

Do you know beams from beans?

1-20 points—You'll use a random wire 'til the day you die.
21-40 points—You actually believe that mini-beams get out as good as a monobander.
41-60 points—You'll always be safe and comfortable with your vertical.
61-80 points—You have a 40-foot tower with a tribander.
81-100+ points—"Antenna Farmer."

CONTESTS



Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

IPA CONTEST

Contest periods are:
0000 to 0300, 0700 to 1000, and 1400 to 1800 GMT on both days, November 7 and 8

The International Police Association Radio Club (IPARC) United States Section is sponsoring this year's contest. Participants are eligible to work the Sherlock Holmes Award (SHA) and the contest is open to all radio amateurs and SWLs. Use all bands on CW and SSB. No crossband or crossmode contacts are permitted. For a contact to be valid, one of the two stations must be an IPARC member. Each station can only be worked once per band.

EXCHANGE:

Non-members send RS(T) and serial number. IPA members send "IPA," two-letter state abbreviation, RS(T), and serial number. US stations will also send two-letter state abbreviation.

FREQUENCIES:

CW—3575, 7025, 14075, 21075, 28075.

SSB—3650, 3775-3800 (European DX), 7075, 14295, 21295, 28650.

SCORING:

Every completed QSO counts 2 points on 80 and 40 meters, 8 points if DX on 80 or 40 meters, and 4 points for all contacts on 20/15/10 meters. The multiplier is the total number of IPA countries and states worked per band.

For IPA members only, an IPA country and each US IPA state will be counted for multiplier and QSO only if an IPA station in that country/state has been worked. QSOs with DXCC countries or US states which are not

listed in the IPARC membership list count only 1 point and do not count as a multiplier.

ENTRIES AND AWARDS:

Each IPA member, non-member, and SWL with the highest score will receive a certificate and will be honored in the Award Chronicle of the International Poice Association Radio Club. Entries must be postmarked no later than December 31st and sent to: IPARC, Thomas D. Jenkins WA8VDC, 3327 Cloverdale W.B., Monroe MI 48161 USA.

Copies of the SHA rules, IPARC World Membership List, SHA application sheets, or contest log sheets are also available if you send an SASE to the above address.

ANTIGUA & BARBUDA INDEPENDENCE OSO PARTY

Starts: 0000 GMT November 7
Ends: 2400 GMT November 8

The members of the Antigua Amateur Radio Society are planning a QSL Party to mark Antigua and Barbuda's independence. All amateurs are invited to participate. For an attractive certificate, work four Antigua stations on any band and in any mode during the weekend. Then submit a copy of your log showing the callsign, signal report, time of contact, and band. Include a self-addressed envelope and $1.00 US to cover postage of certificate. The new operating prefix will be V2A.

FREQUENCIES:

SSB—1825, 3790-3840, 7165-7250, 14180-14300, 21150-21300, 28500-28700, 29600 FM.

CW—30 kHz above the bottom of each band.

Send all applications to: Independence QSL Party, Box 550, St. John's, Antigua, WI.

INTERNATIONAL OK DX CONTEST

Starts: 0000 GMT November 8
Ends: 2400 GMT November 8

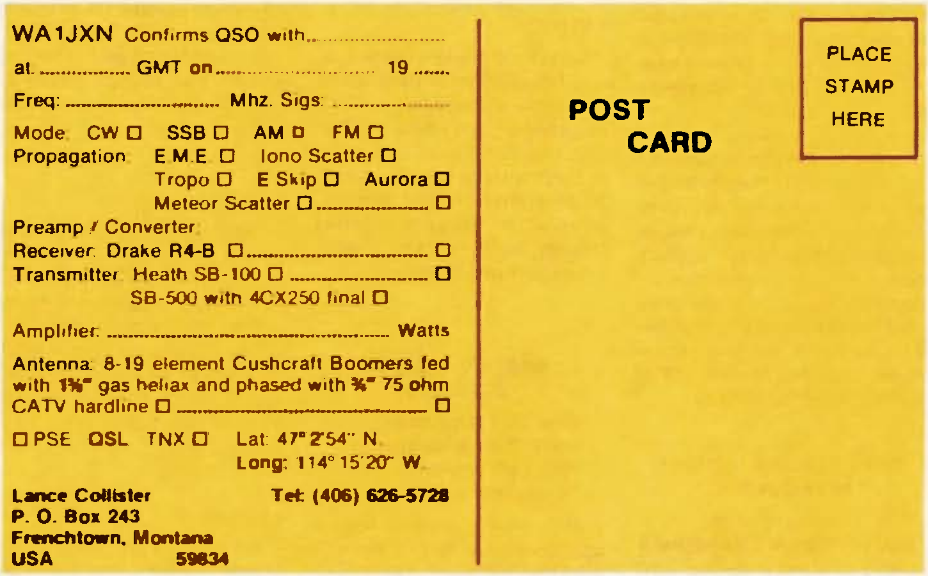
Participating stations work stations of other countries according to the official DXCC country list. Contacts between stations of the same country count only for multipliers, but have no OSO point value. Each station may be worked once on each band. Use all bands, 160 through 10 meters, on phone or CW. Crossband or crossmode contacts are not valid. Operating categories include: A—single operator, all bands; B—single operator, one band; C—multi-operator, all bands. Any station operated by a single person obtaining assistance, such as in keeping the log, monitoring other bands, tuning the transmitter, etc., is considered as a multi-operator station. Club stations may work in category C (multi-op) only.

EXCHANGE:

RS(T) and 2-digit number indicating the ITU zone. Please note the ITU zones are quite different from the ARRL zones! For a list and map of the ITU zones, send 2 IRCs to the entry address listed below.

SCORING:

Each QSO counts one point, or 3 points if with an OK station. Final score is QSO points times



QSL OF THE MONTH: WA1JXN

This distinctive QSL card reflects WA1JXN's enthusiasm for two meters. There are eight 19-element Cushcraft Boomers fed with gas-filled heliax line. Here is how Lance got this dramatic shot: "I shot a photo of my 2-meter antenna at night with floodlights, using high-speed film. After printing it on high-contrast paper (#6), the image was reversed to make it look positive (again on high contrast paper). The result was a ready-for-printing piece of artwork.

Note the detailed information about VHF propagation modes.

If you would like to enter the contest, put your QSL *in an envelope* and mail it along with your choice of a book from *73*'s Radio Bookshop to *73 Magazine*, Pine Street, Peterborough NH 03458, Attention: QSL of the Month. Entries which do not use an envelope (the Postal Service does *occasionally* damage cards) and do not specify book choice will not be considered. Sorry.

the total number of ITU zones worked on each band.

ENTRIES:

A separate log must be kept for each band and must contain the full data. The log must contain in its heading the category of the station (A,B,C), name, callsign, address, and band(s) used. Also show the total number of contacts, QSO points, multipliers, and total score. Each log must be accompanied by the following declaration: "I hereby state that my station was operated in accordance with the rules of the contest as well as all regulations established for amateur radio in my country, and that my report is correct and true to the best of my belief."

A certificate will be awarded to the top-scoring operators in each country and each category. The "100 OK" Award may be issued to stations for contacts with 100 OK stations, and "S 6 S" Awards or endorsements for individual bands may be issued to a station for contacts with all continents. Both awards will be issued upon a written application in the log and no QSLs are required. Logs must be postmarked no later than December 31st and sent to: The Central Radio Club, PO Box 69, 113 27 Praha 1, Czechoslovakia.

DARC CORONA 10-METER RTTY CONTEST

Contest Period:
1100 to 1700 GMT November 8

This is the last of four tests during the year that were sponsored by the DARC eV to promote RTTY activity on the 10-meter band. Use the recommended portions of the 10-meter band.

EXCHANGE:

RST, QSO number, and name.

SCORING:

Each station can be contacted only once. Each completed 2-way RTTY QSO is worth 1 point. Multipliers include the WAE and DXCC lists and each district in W/K, VE/VO, and VK. The final score is the total number of QSOs times the total multiplier.

AWARDS:

Plaques will be awarded to the leading stations in each class with a reasonable score present. Operating classes include: Class A for single or multi-op, and Class B for SWLs.

ENTRIES:

Logs must contain name, call, and full address of participant. Also show class, times in GMT, exchange, and final score. SWLs apply the rules accordingly. Logs must be received within 30 days after the test. Send all entries to: Klaus K. Zielski DF7FB, PO Box 1147, D-6455 Erlensee, West Germany.

NORTH CAROLINA QSO PARTY

1700 GMT November 14 to
0200 GMT November 15
1200 GMT November 15 to
0100 GMT November 16

This year's party is again sponsored by the Alamance ARC and has been expanded to include new categories and awards. The same station can be worked on each band and mode. Crossband and repeater contacts are not permitted. NC stations may work each other for QSO and multiplier credit.

EXCHANGE:

RS(T) and NC county or ARRL section.

FREQUENCIES:

SSB—3980, 7280, 14280, 21380, 28580.
CW—3560, 7060, 14060, 21060, 28060.
Novice/Tech—3720, 7120, 21120, 28120.
VHF—50.050, 50.110, 144.050, 144.200.

SCORING:

NC stations count one point per QSO and multiply total by sum of ARRL sections (73 maximum) and NC counties (100 maximum) worked. DX contacts count only for QSO points.

Others count 2 points per NC contact and multiply total by number of NC counties worked (100 maximum).

AWARDS:

1982 US *Callbook* and certificate to overall top NC and out-of-state single-operator scorer. Certificates to top scorer in CW, SSB, mobile, VHF, and Novice/Technician categories in each ARRL section and NC county. Name of top Alamance ARC member added to perpetual trophy.

ENTRIES:

Send logs and summary sheets showing essential details and certification. Include two 18-cent stamps for results. Mailing deadline is December 12th; send to: Bob Wang KQ4M, PO Box 777, Hillsborough NC 27278.

EUROPEAN DX CONTEST—RTTY

Starts: 0000 GMT November 14
Ends: 2400 GMT November 15

Sponsored by the Deutscher Amateur Radio Club (DARC). Only 36 hours of operations out of the 48-hour period are permitted for single-operator stations. The 12 hours of non-operation may be taken in one but not more than three periods at any time during the contest. Operating classes include: single-operator, all band and multi-operator, single transmitter. Multi-operator, single-transmitter stations are only allowed to change band one time within a 15-minute period, except for making a new multiplier. Use all amateur bands from 3.5 through 28 MHz. A contest QSO can be established between all continents and also one's own continent. However, QSOs and QTC traffic with one's own country is not allowed! Each station can be worked only once per band.

EXCHANGE:

Exchange the usual six-digit number consisting of RST and progressive QSO number starting with 001.

SCORING:

Each QSO counts 1 point. Each QTC (given or received) counts 1 point. Multipliers will be counted according to the European and ARRL countries list. The multiplier on 3.5 MHz may be multiplied by 4, on 7 MHz by 3, and on 14 through 28 MHz by 2. However, contacts within the same continent only count as a multiplier of one per band (including 80 and 40 meters). The final score is the total QSO points plus QTC points multiplied by the sum total multipliers.

QTC TRAFFIC:

Additional point credit can be realized by making use of the QTC traffic feature. A QTC is a report of a confirmed QSO that has taken place earlier in the contest and later sent back to another station. The general idea is that after a number of stations have been worked, a list of these stations can be reported back during a QSO with another station. An additional 1 point credit can be claimed for each station reported.

A QTC contains the time, call, and QSO number of the station being reported, i.e., 1300/DA1AA/134. This means that at 1300 GMT you worked DA1AA and received number 134. A QSO can be reported only once and not back to the originating station. A maximum of 10 QTCs to a station is permitted. You may work the same station several times to complete this quota, but only the original contact has QSO point value. Keep a uniform list of QTCs sent. QTC 3/7 in-

squelch tale

Published monthly by the CHICAGO FM CLUB Inc a non-profit radio amateur club

NEWSLETTER CONTEST WINNER

The winner for the fourth month of *73 Magazine*'s Club Newsletter Contest is *Squelch Tale*, published by the Chicago FM Club. The judges were impressed by both the informational content and the newsletter's eyecatching appearance. Once a publication's staff has gathered all the club news, technical articles, and advertising, their job has only begun. Creating an appealing look is one way to encourage readers to look at each and every page of the newsletter. Even if your club has a shoestring budget, there are several inexpensive, simple ways to gain that professional look.

The simplest method of generating the first draft for a newsletter is on a typewriter. Obviously, an electric machine with a good ribbon will generate nicer copy than an inexpensive manual typewriter. You can go an extra step and "word process" the contents of your next newsletter. A word processor is a computer-based system that allows a user to organize, edit, and print out the copy in exactly the form you want. Corrections don't require messy correction fluid; you just backspace and retype the correct version. As a bonus, most word-processing systems will allow you to right justify the printout. This means that both the left and right sides of a column will line up, just like the text in this magazine. Word processors are becoming common fixtures in many offices. Perhaps a club member with a microcomputer can help you out. The club should supply its own paper and spring for a new ribbon now and then.

If your club won Field Day, you would want to tell the world—somehow typewriter-sized print wouldn't do the job very well. Headlines that have a bold, yet pleasing appearance can be made from dry transfer lettering. Art supply and stationery stores usually have several sizes and styles to choose from. Each headline and article can be prepared individually. Then the pieces are combined into one-page layouts, much as you would assemble a puzzle. This process, known as paste-up, will have a great influence on the final appearance. The time and money spent here will have a direct reflection on the end result. Your local library should have a book that discusses the details of production, or you can get some advice from the experts at a printer or copy shop.

Newsletters like *Squelch Tale* have a carefully considered layout that is consistent from issue to issue. The material is not crowded, nor is there a lot of white space. Each issue is headed by the newsletter logo; once you get a good logo you can use it again and again. Short filler items can be used to fill those corners that are left over. You can even incorporate some flashy graphics on the part of the newsletter where the address and postage go.

There are several ways that a newsletter can be reproduced. Very small organizations probably can get away with photocopying. The next step up is spirit duplicating and mimeographing. For slightly more money, you can use offset printing. You provide a clean, sharp original for each page in the newsletter. The printer uses these to make inexpensive "plates" that go on the press. The offset method gives you total control over the layout; changes can be made by pasting new material over the old. If your budget permits, offset printing will allow you to incorporate two or even three colors of ink. And, for the special occasions when only photographs will tell the story, you can get crisp black-and-white reproduction.

To produce a top-notch newsletter, the staff needs two kinds of people. Besides the individuals who gather and edit the news, the staff should have artistic types. Hopefully, your club can find a good printer to round out the group. When shopping for a copy service, look at both price and quality. Happy publishing!

dicates that this is the 3rd series of QTCs sent and that 7 QSOs are reported.

AWARDS:

Certificates to the highest scorer in each classification in each country, reasonable score provided. Continental leaders will be honored with plaques. Certificates will also be given stations with at least half the score of the continental leader or with at least 250,000 points. The minimum requirements for a certificate or a trophy are 100 QSOs or 10,000 points.

ENTRIES:

Violation of the rules or unsportsmanlike conduct or taking credit for excessive duplicate contacts will be deemed sufficient cause for disqualification. The decisions of the Contest Committee are final. The use of the log sheets of the DARC or equivalent is suggested. Send a large SASE to get the wanted number of logs and summary sheets (40 QSOs or QTCs per sheet). SWLs apply the rules accordingly. Entries should be sent no later than December 15th. North American residents may send their applications and logs to: Hartwin E. Weiss W3OG, PO Box 440, Halifax PA 17032 USA. Others may address entries to: Klaus K. Zielski DF7FB, PO Box 1147, D-6455 Erlensee, West Germany.

EUROPEAN COUNTRY LIST:

C31, CT1, CT2, DL, DM, EA, EA6, EI, F, FC, G, GC Guer, GC Jer, GD, GI, GM, GM Shetland, GW, HA, HB9, HBØ, HV, I, IS, IT, JW Bear, JW, JX, LA, LX, LZ, M1, OE, OH, OHØ, OJØ, OK, ON, OY, OZ, PA, SM, S, SV, SV Crete, SV Rhodes, SV Athos, TA1, UA1346, UA2, UB5, UC2, UN1, UO5, UP2, UQ2, UR2, UA Franz Josef Land, YO, YU, ZA, AB2, 3A, 4U1, 9H1.

HAM HELP

I would like info on 10m FM conversions (except *73* articles and K9EID's book), especially for Japanese HF rigs; 29-MHz amplifiers; access details for 10 FM repeaters and the use of CTCSS and touchtone. All letters answered.

WHAT'S UP, DOC? DEPARTMENT

I can't go into specific details at the moment, but suffice it to say that the long-awaited "clean sweep" of our amateur bands is on to rid them of all sources of willful and malicious interference. Actually, it started to get up a full head of steam last spring, mainly on the west coast, but now reports are coming in that deal with the issuance of warning letters, official citations, and show-cause orders on a rather grandiose scale nationwide. To say that the FCC is on the warpath is definitely an understatement.

Since there will probably be ongoing litigation in regard to many of the show-cause orders, i won't report on any specific case at this time. i can say that the clean-up is not being limited to repeater jammers and users of foul language. Those who interfere with HF nets and other organized amateur operations have also come under the gun of the FCC's enforcement branch. Nor do I foresee any end to these rigorous enforcement policies in the near future. Also, most amateurs I have spoken with are delighted at this turn of events. They feel that it's about time that those who claim to regulate our service show that they have the ability to make their rules stick.

But there is the other side. Some of those the FCC is clamping down on claim that the Commission has no right to regulate what they say over the air, in what way they say it, or who they say it to! In essence, their claim is one of having "the right to yell fire in a crowded theater," and in their minds it becomes your responsibility to ignore what they say. I've heard unconfirmed rumors that a number of those served are banding together, pooling financial resources, and vowing a fight on the matter to the US Supreme Court. Other rumors say that the American Civil Liberties Union has been approached for representation on the basis that the current enforcement action by the FCC violates various aspects of individual civil rights.

And here's the funniest one of all. Again, the rumor mill has it that the majority of those now in trouble with the FCC blame the ARRL for their plight. I consider this ironic in that the only thing the League has done thus far has been to form another *ad hoc* committee. If the League is responsible for the clean-up, it's news to those who are really the responsible parties. Who are they? If you have followed this column for any length of time, I think that names and callsigns like Joe Merdler N6AHU and Ray Frost WA6TEY are familiar. While the ARRL formed committees, these amateurs and others took to the world of politics. They worked through their legislators to make enforcement of the amateur rules a top priority with the FCC. It has now become quite clear that they have been successful.

The end of the fight to combat the problem is not yet in sight. As has been heard on the ham bands many times, by many of you first hand, jammers have openly stated that taking their licenses away won't keep them from jamming. And, as one expert on the subject has said, "Don't be surprised to see things get a lot worse before they get any better. It may take putting one of these jokers behind iron bars for a few years to get the point across that laws were made to be respected and not broken." I don't see things getting very much better in the near future, but we can hope. At least an important first step has been taken, but it's going to be a long time before we really see the light of day.

THE SCRRBA REPORT, PART II

Last month we began what might best be termed a mini-series about the future of UHF voluntary frequency coordination in southern California, and the problems being faced by this area's UHF coordination body, the Southern California Repeater Remote Base Association. As I said last month, this report, compiled by Gordon Schlesinger WA6LBV of the SCRRBA Technical Committee, may be primarily directed at the UHF system operators of this area, but it holds merit for any coordinator or coordination council, especially those in the position of having far more relay systems looking for homes than channel pairs available. Basically, that's the problem facing SCRRBA and many other coordination organizations nationwide.

SCRRBA is not an organization known for chasing its own tail. It is basically a very quiet organization that has historically taken a very methodical approach toward voluntary coordination. I suspect that is the reason for its longevity and its success rate. Everything is carefully researched, and this report is no exception. We continue where we left off last month.

THE VALUE OF A SOUTHERN CALIFORNIA UHF CHANNEL PAIR

A few areas of the country list only one or two UHF channels in use in an entire state. In these areas, coordination of a UHF channel pair may well be as informal as telephoning a frequency coordinator and asking: "Should i use 449.100, .200, .300, or .400?" A decision is quickly made and recorded.

In southern California, those system operators who originally obtained channel pairs for their relay stations from CARC coordinators in the 1960s and early 1970s may remember that at that time our coordination procedures were not much different. While even then there was a significant population of the 440-450 MHz portion of the band, we were not yet near 197 operational systems. At that time the spectrum appeared boundless, and coordination was an easy matter. A telephone call would accomplish the process, and there was little if any paperwork involved; several channel pairs at a time could be requested, received, and "warehoused."

A current problem in frequency coordination arises, however, because some of our system owners have not yet realized that those golden days have ended. With our current massive occupancy of the band, every channel pair is now quite valuable. Every pair is in demand. Every pair has a potential applicant ready to establish a machine upon it. The coordinated use of a UHF channel pair is no longer a casual matter to be ignored or taken for granted.

There are three different groups of mobile relay system operators involved with UHF frequency coordination: operators of presently coordinated systems, applicants for coordination for new UHF systems, and the SCRRBA Technical Committee. Every group views the situation from a different perspective, although all have (or should have) a common interest in seeing the frequency coordination process from the standpoint of each of these groups.

Some of the owners of presently coordinated systems may have the least accurate perception of the current state of our band. In a sense, this is understandable. Many of them undertook coordination some time in the past, perhaps more than 10 years ago. They established their machines, have operated and improved them over the course of the years, and some have not kept in touch with the progress in the development of the band. Consequently, in some cases their notions about band utilization are outdated. Others, by contrast, have a very fine understanding of current trends and problems.

THE APPLICANT FOR NEW FREQUENCY COORDINATION

The availability of programmable scanners means that anyone can develop a list of apparent activity on the 70-cm band. (Ed. note: This holds true for 2 meters, 6 meters with some scanners, and even 220 when a converter is used ahead of the scanner.) New scanner owners often begin keeping "researched lists" showing, as best they can determine, which channels are in use and how they are identified. This information could be used to program scanners to listen to "interesting machines," but it can also be used as a guide to which channel pairs appear to be unused. It's therefore not surprising that the Technical Committee receives requests for exact frequency pairs which are desired. However, the vast majority of these requests cannot be coordinated as requested.

The Technical Committee is

well aware of the existence of scanner-generated research lists. From time to time we receive copies of various editions. The accuracy of these lists is generally, at best, poor. Some of them are correct... as far as they go, which is not very far at all. Others are grossly inaccurate, sometimes to the point of being laughable. A few are badly outdated. All attempt to give the appearance of being "seriously professional." Such researched lists, however, are totally insufficient as bases for reasonable channel selection. Effective data, not obtainable by monitoring, are mandatory for any accurate and effective coordination action.

It must be stated that the chief function of the Technical Committee, as with any frequency coordination body, is to maintain an accurate, complete, and timely record of all UHF relay activity in southern California. The Technical Committee record was initiated by the inclusion of the old CARC UHF coordination files, which themselves were begun nearly 20 years ago. To those records have been added the details of each frequency coordination which the Technical Committee has performed, as *well* as the corrections, deletions, and updates which we have received.

The data base from which the Technical Committee coordinates consists not only of a chart of frequency assignments, but also the complete set of technical and operational data and histories for each relay system. Both parts are necessary for performing accurate frequency coordination; neither part by itself is sufficient.

The data base is not perfect. No tabulation of activity as diverse as UHF mobile relay in southern California can be. But it is a data base which is... and must be far, far more accurate than anything else available. It is, fundamentally, a data base upon which frequency coordination of additional systems into an existing congested environment can be performed, with a considerable degree of confidence that the new station can begin operation without creating or experiencing substantial interference.

The Technical Committee has seen some past instances of new UHF mobile relay station operators, possessing copies of researched lists (or under the counseling of someone who does), merely selecting a "free pair" for themselves and going on the air without consulting the committee. The "self-coordination" obviously looked good, at the time, to the individual who performed it, else why would that particular pair have been chosen? Nevertheless, in an environment as congested as southern California UHF is today (Ed. note: Also 2 meters and 1¼ meters), there are no longer any "free pairs." Inevitably, there is another co-channel machine somewhere else in the region, and eventually the operators of the two machines will discover each other. Problems then ensue, typically resulting in a large expenditure of time and money before a resolution is effected. With over 300 relay stations in operation, an initially small problem in one corner of the region has the potential of becoming a much larger problem affecting a large number of systems and operators throughout all of southern California. Each system owner must realize that he has a personal stake in the entire coordination system, a system which is now too complex to be forgiving of small errors or transgressions.

Each potential applicant for UHF (Ed. note: Or any) frequency coordination, possessing a researched list and tempted to bypass the usual coordination process, must ask himself: "Am I performing coordination from a data base which contains at least 320 separate entries?", and "Do I have accurate technical data for the relay stations on my list?" If the answer is "no," then the individual must realize, or be convinced, that he is operating *from* a position of ignorance and that his actions are a potential threat to all members of the UHF community. We can no longer tolerate self-coordination; those days are gone!

THE TECHNICAL COMMITTEE AND THE SCARCITY PROBLEM

(Ed. note: Here is the heart of any voluntary frequency coordination effort. It is the ongoing dedication of people who serve as coordinators or committee members that pulls it all together. If they fail, it's a failure for all amateurs in a given area. In SCRRBA, we see the epitome of a successful coordination body. Many of those serving in its organizational structure have done so dating back to the CARC years. Building and nurturing a successful coordination body takes time, dedication, and understanding. The lack of abdication by those who have joined with SCRRBA is strong testimony for the people and principles with which the organization was founded.)

The vast increase in the number of coordinated systems, together with the relatively constant demand for new channel assignments, has greatly increased the workload of the Committee. This increased workload is straining the Committee's ability to provide accurate and timely new coordinations and has prompted the writing of this special report.

While much of the Committee's work is done on a continuing basis, including handling incoming and outgoing correspondence, updating records, conducting band-monitoring studies, etc., all actual coordination actions are accomplished only at Committee meetings. It has been the Committee's practice to try to meet relatively often in order to keep on top of the coordination applications. However, increasing travel costs have mandated somewhat less frequent meetings. In order for the Committee to function, members must assemble at one location. (Out here, this usually means either Los Angeles or Orange County.) Members travel from as far away as San Diego and Santa Barbara to attend; this can mean as much as 5 hours of driving time for some, with *no* reimbursement of expenses. Since SCRRBA coordination is of the voluntary, amateur-sponsored kind, Committee meetings occur at night or on weekends. Every meeting entails loss of leisure time which could be spent with family or working on radio systems.

Hand in hand with the occupancy of the UHF band (Ed. note: Again remember that the band in question depends upon your own particular geographic locality...this is written in regard to southern California UHF, but in this region it could be applied to 10 meters, 2 meters, and 220. In a year or so, we will apply it to six meters as well.) has gone increased length of Technical Committee meetings. Whereas it formerly required 15 minutes to handle the average request for coordination, including selecting an appropriate frequency pair and entering the action onto the coordination data base, it now averages one hour to do the same job. While a few applications can still be handled in the previous 15-minute period, others may require in excess of 2 hours if the application is a difficult one. Consequently, Committee meetings are always marathon affairs.

SUMMARY TO DATE

In parts I and II of the SCRRBA Special Report, we have seen the problem facing the coordination body for one band in a highly populous geographic region. First we had a general overview, and now we've had direct insight to the problems of frequency coordination. Unless you have served on such a committee (and your editor spent 8 years with the Southern California Repeater Association in various functions), you have no idea what performing this seemingly simple task entails. I know what it is to give of my personal time, doing so week after week and year after year. I know firsthand of the hardships involved in being a member... an active member of such an organization.

I also know that it is impossible for such organizations to make everyone happy. The coordination process dictates that somewhere along the line some individual or group will be unhappy if for no other reason than the channel pair they long to possess is already in use by another.

Reality dictates that for a voluntary coordination body to be successful, it must be prepared to face any eventuality. For instance, with many areas of the nation already saturated with FM two-meter activity, many manufacturers seem intent on making 450 the next big VHF/UHF marketplace. There's nothing wrong with this in my book, as this is the name of the game in our free enterprise system. But even they must be accountable to the amateurs of a given area, and there are some geographic locations that do

not lend themselves to UHF transient relay mobile communication. Southern California is one of them.

Of the some 320-odd UHF relay systems now operational in Southern California, only 13 are "open" or "public access," as SCRRBA refers to them. Of these, only 6 serve Los Angeles proper. All the rest are "private" category machines that do not welcome transient operators even if the transient happens upon the proper CTCSS access. I may be wrong, but unless some drastic changes happen to the thinking of most UHF operators, changes I doubt will take place in the foreseeable future, I doubt if any major inroads will take place on 450 by the average ham in this region. The very structure of the band precludes it. The manufacturers of new equipment may and hopefully will find success in other major markets, but I would not want to bet my advertising budget on southern California. The place is just too set in its ways.

But even SCRRBA recognizes this problem, if one deems it to be a problem, and is planning on ways to cope with it. SCRRBA is perhaps the most successful voluntary coordination body in the nation mainly because they have an eye on that famed expression, "Plan Ahead." We will conclude this three-part mini-series come January, since next month we have a special Christmas column for you. Till then.... a Happy Thanksgiving from those of us who write the late shift from Los Angeles.

Kinnelon NJ 07405

The editors of *QST* saw fit to include in the Correspondence Section of the September issue a letter that really opens a can of worms that needs to be examined with care. The writer of the letter takes the position that the neighbors of an amateur are entitled to enjoy a vista uncluttered by antennas. He equates this right with his own right to insist that nobody play loud rock music after 1 o'clock in the morning. The comparison, aside from being both odious and foolish, is mischievous and can cause trouble. For if ever we allowed ourselves the luxury of blithely permitting such specious arguments to be injected into the general question of community zoning, we would be begging for the establishment of highly dangerous precedents that could be used over and over again by unsympathetic, hostile local government groups.

What possible analogy can be drawn between noisy public disturbances after midnight and the inherent right of the possessor of a federal license grant to exercise the privilege conferred through the issuance of the license? There is no analogy; the two are as unalike as bananas and stalks of celery!

The writer further states that he purchased his home "knowing full well that no flagpoles, clotheslines, garbage cans, *or outside antennas* were allowed." Not allowed by whom and by what sort of a covenant? If he is referring to the builder of a development who establishes such sanctions as an integral part of his plans, then he is correct. But in all other cases he is wrong. It may be proper for a community to insist upon certain limits of one sort or another, based upon sound engineering and safety, and upon avoidance of property line infringement, but it is improper for the community to condemn and outlaw all antennas generically. The term is literally a catch-basin, totally unspecific. It runs a broad gamut, embracing anything and everything from the simple dipole or whip through yagis, quads, rhombics, long wires, phased arrays of dozen of types and configurations, and some which have not even yet been devised! The sentence betrays an astonishingly naive attitude that one would never have thought would be expressed by any mature amateur.

In the first place, such disallowances have been successfully beaten down in test after test in the courts. Communities frequently attempt to sanction various uses of property by owners. If the individual is foolish and pliant enough to accept it without raising a ruckus, the town or county gets away with it. So what this man describes as "knowing full well" is merely an admission that he is willing to turn up his toes and play dead for the zoning board. He ought to have written instead: "...knowing full well that the town disapproved of antennas, but that this disapproval could not stand up if I chose to fight against it."

Now, in the matter of "laws that make others pay to prevent our hobby from being a nuisance to them," the writer is entirely balled up. For years it had been demonstrably evident that the manufacturers of TV receivers, hi-fi units, and other electronic entertainment devices willfully and deliberately omitted adequate filtering and shielding in order to make larger profits. In a vast majority of cases involving complaints of RFI and TVI to the Federal Communications Commission,the amateur stations concerned were proven to be blameless, and the devices of the complainants were shown to be at fault. Further, it can be shown that literally hundreds, if not thousands, of appliances of every sort have been made and sold which radiate interference in violation of radio regulations. Laws which compel compliance with state-of-the-art technological standards are not inappropriate in any way, for they merely force manufacturers to do what they are supposed to do in the first place.

I am not being fractious; I am just growing a bit weary of the arguments of hams who ill-advisedly want to run and hide, who feel that they would rather switch than fight, who think that it is best not to make waves. I don't know just how important his radio hobby is to this particular writer. But I do know that to hundreds of thousands of us it is very important indeed. We are not about to play the "shrinking violet" every time some local political hack or shyster waves an arbitrarily written local ordinance in our faces and threatens us with dire consequences. We are willing to fight for the rights conferred along with the license grant, a right which generally supersedes the petty, picayune statutes formulated by persons with neither any understanding of the Bill of Rights nor any inkling of the splendid record of public service and innovative contributions to the art of communications run up by the amateur service.

Incidentally, I think it is somewhat interesting, if only coincidental, that the same issue of *QST* carries an editorial on the subject of RFI, as well as a report on a recent reversal on appeal where there had been a conviction on one of these malignant regulations of which I have been speaking.

This chosen avocation of ours did not arrive at its present state of popularity and growth through the docility of a pack of passive dilettantes. We have a long tradition of passionate involvement and dedication to our hobby, notwithstanding the phlegmatic indifference of a few among us, who, like the writer of that letter, not only back down in the face of challenge, but also convince themselves and attempt to convince others that it is right and proper to do so.

On the day that amateurs become willing to accept the repression of our activities without a murmur, we will be witnessing the beginning of the end of ham radio. And if we ever become resigned to the idea that we exist merely through the sufferance of others, that our operation is contingent upon tolerance from those who are prejudiced against us, then we will richly deserve to be flushed right down the drain! Among other qualities demanded of us, one that stands high is militancy. For just as in life in general, the continuance of ham radio also depends upon the exercise of the instinct for self-preservation.

The only thing in the letter with which I agree is the last paragraph, but even that is somewhat flawed because he implies that we should be reacting to pressure from the so-called anti-antenna movement through technological growth. The fact is that such growth has always come about through the natural curiosity and inventiveness of the amateur community rather than as a reaction to the pressure of outside forces. This process will continue. And the adversity posed by the activities of our foes will merely intensify and reinforce it.

In passing, I must observe that this is the very first time in a long and rewarding relationship with the hobby that I ever heard of any amateur who equated "making the community more beautiful" with the elimination of antennas! I never met a ham who failed to view a fine antenna installation as a thing of beauty.

Well, perhaps the answer is that this particular ham is not as dedicated to the hobby as most of us are. Say, listen... maybe he's a real-estate developer or the owner of a beachfront condominium building. He sure sounds like one!

Enough of this, except to reiterate my wonderment toward the impulse that caused the *QST* editors to select this particular letter out of the hundreds which must arrive every month. Perhaps it was their way of playing "devil's advocate" and they hoped to provoke dialogue on the subject. If this is so, then I politely tip my hat in their direction. For they have afforded me an opportunity to express some thoughts on it, too.

I sincerely trust that others will have detected the sour notes in this masochistic, self-flagellating cantata of capitulation to our adversaries. And I hope that there will be a flood of letters written to *QST* to belie the false contentions of the writer. They merit the condemnation of every amateur who is interested in preserving ham radio and protecting it from the sniping to which it is constantly exposed. The very notion of bowing our heads submissively and failing to fight against unfair antenna sanctions should be repugnant to every amateur. We must not allow ourselves to become second-class citizens simply because others happen to dislike us or our chosen hobby. As the old British motto puts it: Let right prevail.

SALUTE TO CW

Who needs it? The answer is: *you* and everybody else. Why? Because it separates the ham from the rest of the crowd and all those big-mouth, never-shut-up screamers and list operators. Let's have a look at a few points.

1. CW is the most reliable mode of communication. It can be copied at times when even SSB signals and other modes become unreadable. It is quite common to find that when the SSB signals are just fading out into the noise, stations switch to CW and it is like magic—signals are still readable and the difference is equivalent to 2-3 S-units. This is the reason why CW is used where there is the need to communicate at very low signal levels, such as VHF moonbounce, 160 and 80 DXing, remote area DXpeditions, etc.

2. It takes a little bit of devotion and work to master the speed. This is what separates the true-blue ham from those who are in the hobby to mess things up and deregulate it to the 27-MHz "state of the art."

3. Some are saying that CW is the old-fashioned mode, outdated and dying. Well, I think we are in for big revival. It is not dying; there are still a number of stations that can not afford SSB or more sophisticated rigs, and they have to home-brew their equipment. A CW rig is the easiest thing to build. Now with the explosion of computers, we will see more and more operators going back to CW and away from all those list undertakings. We can perhaps standardize one or two speeds on CW and let the computers talk to each other or to people. The wonderful thing is that they are compatible and could be fully automated. It also makes more sense to use CW than RTTY or ASCII, mainly for the possibility of communicating with those who have only ears. The present state of the art allows us to use fairly simple decoders and with the proper filtering and stability of today's rigs, it should be a relatively easy thing. Not to mention that keyboards make the CW machine quality perfect and easy to use.

4. Coherent CW is making its inroads and is offering another about 12 dB of signal-to-noise advantage. This offers another step of improvement. By narrowing the bandwidth on the receiver, we are making more room on the band; stations are able to get closer to each other.

5. There is a breed of operators who are operating almost exclusively on CW, away from the lists, etc. You can't help but feel much better when you tune down below the phone bands. The old ham spirit still lives there.

6. Numbers of expeditions have found that they can work the stuff much faster on CW than on phone. Sound strange? Not really. You can separate the stations much better on CW, especially when the pileups tend to get very heavy. With all those compressors adjusted for 20 dB of compression, there is more crud on the band than modulation. Sometimes they can even manage to QRM their own signals. You can quite often hear the background noise louder than the actual operator's voice.

So don't throw your key or keyer away; whenever you feel like it, give it a try. Besides, a number of countries and expeditions operate only CW. So be ready when you need that one.

One note to CW operators: Some rigs have drive control on the transmitter. It is important to set the level just below the point where there is no more increase in the transmitter power when increasing the drive level. It may seem that it does not matter, since there is no more signal going out. It makes a big difference on the signal quality; clicks and wide signals start coming out of the transmitter and give you a bad image among the fraternity. So be sensitive to that level setting and keep it clean!

Another note on the technical side: Be aware of your frequency. With the SSB rigs, good filtering and single signal reception, it is important to know if you are equivalent to USB or LSB on the filter. This is important for the receiver calibration, especially when you want to operate close to the band edge. The best thing is to use the zero-beat frequency. Some rigs use USB and some LSB for CW, so sometimes there could be over one or two kHz difference.

It is also important to know your transmitter offset on CW. Most rigs have offset around 1 or 1.4 kHz. When you operate transceive and you prefer tone around 500 Hz, when you call the stations you would be about 800 Hz or so out. If he is using a sharp CW filter, he might not hear you, especially when the bands are crowded (more important in a contest!). The best thing with the transceiver is to use RIT with the receiver and offset it in order to match the frequencies on receive and transmit. It is not uncommon to find some stations off frequency by as much as 3 kHz. Most hard-core CW operators use a separate receiver/transmitter combination, and there you can tell exactly where you are. So if you have a transceiver, it pays to find out where your signal is on transmit, and if it needs adjustment, most rigs can be adjusted by trimming the CW transmit offset capacitor.

Vince Thompson K5VT

Vince is a real delight for those hard-core CW operators.

Vince is making an extensive tour through Africa and has put a number of very rare countries on the air. He operates just about exclusively CW and the operation is first class. No wonder, he belongs to the FOC—the First Class Operators Club. He is working them fast—that means at high rates and good high-speed CW. He follows the propagation and tries to adjust his operating hours so he can satisfy just about everybody who needs him. He prefers the 15m band and can be found around 018-025 from the band edges. He usually operates split, listening from 1 to 6 kHz up. QSL cards go to his home call, K5VT.

So far, Vince has put on the air the following calls: 7P8CF, 9Q5VT, TN8VT, 9U5AV, S79WHW, S9VCT. Next on his program were supposed to be: 5V, 5U, TT8, and possibly others.

Bad tongues are saying that Vince goes to see the licensing officer who is ill. Being a doctor, he "fixes" him and the rest is a snap—a license in hand for an otherwise inaccessible rare country. Hi.

Vince is doing an excellent job and has to be congratulated for true high-quality operating and the choice of the countries he has activated.

Some Tips

How does one catch Vince and others that operate in a similar style? Here are some crude recipes:

First you tune across the band and you usually spot the big pileup. There is always a reason for that, so you can start looking for it. Most of the time, that reason is that rare DX is usually sitting a few (3-5) kHz below the bottom edge of the pileup. Then you have to start tuning very slowly and carefully to find him. Slowly, because he is usually coming back in short bursts of calls and reports, and you can very easily pass over him. If you have a rotatable antenna, it is also good to know where is he coming from so you can get enough signal for the receiver if he is weak (like VU7AN). Once you have found him and know who it is, half of the work is done. If you need him, then you have to do the other half—work him.

The most effective way of doing that is to find out his operating style or technique. Where is he listening? Is he picking the calls randomly at different frequencies, or is he going up the band or down? Try to find the stations he is working and establish the pattern. Once you know that, try to "tailgate" the last guy worked on the frequency or just slightly up or down. With a reasonable signal, this is usually the quickest way to work him. It is well worth spending the time to find out the pattern.

Or you can just pick the frequency and keep calling until he finds you. It is almost equivalent to the lottery , but it works, too.

This procedure, of course, applies to the split-frequency operation, which most DXers do use. Those that work on the same frequency get usually snowed under the never-ending pileup, and nobody can even hear them coming back to the stations.

Another important thing is to not call when someone is sending his report; be civilized and let him complete the contact. Otherwise, you will drive the DX away and nobody will get him. I have heard Vince asking the W6. . for his report and not get it, because others just kept calling him. After a few tries he gave up and quit. Proper thing to do.

What a difference in working our Japanese friends. If you ask for a stations with a "J" in the callsign, only the one that has the "J" in the suffix comes back, not the whole of Japan! What discipline and politeness! The net result is that many stations work the rare one and everybody is happy. Can you get the same result if you said: "QRZ W-something?" or "QRZ I-something?" No way, everybody all of a sudden forgets his callsign and actually tries to convince the poor DX that it is him that he has heard. The result? Big mess.

So what will the good operator do? He will throw in his callsign once or twice and wait, giving the DX a chance to come back to somebody. Try it; it works! But we all have to do it. If we try to be the last one in the pileup, then everybody wants that and the result is a never-ending screaming pileup and vanishing DX.

CQ WW DX CW Contest

This contest is a great opportunity to do some fishing for the rare ones and brush up on the rusty CW (oops, Morse code) and also observe some operating tricks and tactics by the big guns.

A number of rare expeditions are being planned and one can easily work his first 100 countries on that weekend. It is always the last weekend in November. Don't forget to send the log from the contest; sponsors always appreciate that.

• • • • •

We are looking for some pictures and stories from the expeditions or any DX stations. So please send pictures and a few lines about yourself. Many are curious to find out how you look and what are you running.

DX NEWS

CEØX San Felix Island. This very rare spot was to be activated by WB1GDQ, N4CNL, WB9AAD, SV1JG, WØAX, and possibly SV1IW. Apparently permission to operate has been granted and the latest info was that they should be starting around October 15th.

Juan Fernandez Island. CEØZAC and CEØZAD, a YL/OM team, are on the island for about three months, starting in September.

FB8WG Crozet Island. Rumored to be on around the 10th of September by a group of French operators.

HS1AMC Thailand. Apparently the bad news from there is that amateur radio activity was again suspended, so we will not hear them for a while. HSØHS operated during the *CQ* WW CW contest.

Belize. A J9 prefix will replace the VP1 prefix.

W6SOT/LX Luxembourg. Please QSL via KA5CCO and not via KA5CCD. Same for his operation as W6SOT/3A.

S9, Sao Tome Island. Activated by K5VT. Another operator should be stationed there very soon. If he obtains his license, he should be active for about two years.

UA1PAM Franz Josef Land. Operator Slava active around 14017 2000Z. QSL via UK3SAB.

VE1AWS/1 Sable Island. Mostly CW; QSL via W3HNK (ran out of VE managers?).

VE1BL/1 St. Paul Island. QSL via W3HNK.

K9MK/VP2A and KN5N/VP2A Antigua. All cards go via K9MK.

VP2MMR Montserrat. Operated by Dick Bash. Makes you wonder if he used his books to get his license. It sounded more like someone from the 27-MHz crowd than the amateur. HI. QSL via KL7IHP.

VP8 South Orkneys. Stations VP8ZR, Denis, QSL via G3KTJ, VP2AJL Op. Ray QSL via Signey Island, Stanley, Falkland Island, and VP8AEV Bob. They are all on Signey Island, quite frequently on 15m around 21272.

VP9CB Bermuda. Please QSL direct or via bureau to VP9CB and not to VE3MPZ/VP9.

Andaman Islands. VU7AN showed up surprisingly. Signals were very weak on the east coast. VE3BMV Razor Beams scored that one. Operation mostly on 15m CW around 21095. QSL via VU2WTR.

VU7 Laccadives. JA group is planning to operate before the end of October.

XZ5A, XZ9A Burma. Still quite active and easy to work. They are showing up on some lists, but also operate "solo" and split on 15 and 20m. Bad news from the ARRL is that apparently those stations are not to be accepted for the DXCC. Some don't care if the ARRL gives its blessing; they simply work them and collect the cards. It seems strange that stations operated by the nationals from the country where they live are not considered "kosher." Do I have to send my license to Newington so all those that worked me can use my QSL cards for the DXCC credit? I would think if there is no doubt about the presence of the station in that country, then it should be OK. Operations by comedians that can travel by boat from NY to Antarctica in 5 hours should be questioned.

1AØKM Sovereign Order Of Malta. Apparently even after the recommendation of the ARRL DX Advisory Committee, this was not accepted as a separate country. Another Muppet show?

3C1MM Equatorial Guinea. Worked on CW early August. QSL via EA1QF.

7Q7LW Malawi. Quite active, mainly on 15m working lists and solo (much faster). QSL cards are being received and are good for DXCC.

Top Ten Most Wanted Countries

According to *The DX Bulletin* (K1TN), the list is: BY, VS9K, XZ, ZA, VU Lac., VKØ, 7O, XU, FB8W, VU7 And. It looks like about two or three can be easily blown off that list before the year's end.

HAM HELP

I am looking for work in the electronics field in the Knoxville, Tennessee, area. Will be able to start February 1, 1982. My experience includes 20 years working on transmitter and receiver equipment from dc to GHz. I have an Extra class amateur license and First Class radiotelephone license with radar endorsement.

Herman F. Schnur
115 Intercept Ave.
North Charleston SC 29405

I have an R336/GRC26 Army radio receiver made in September of 1951, with a tuning range of 1.5-18 MHz.

I would like to convert this unit to an rf generator, vfo, or heterodyne exciter. I hope someone may be able to help me. Any information you can give will be greatly appreciated.

Kevin Neal
Rte. A, Box 221A
Flippin AR 72634

I am in need of help to repair a Canadian No. 19/MK III wireless HF surplus transceiver. The tuning dial is jammed. Any MK I, MK II, and MK III units for spare parts are needed. Also, any conversion info and manuals are needed. Please write and let me know what you've got. I'll reimburse printing and postage expenses. Thank you.

Jim Miyagawa WD8NRG
1529 Woodland
Portage MI 49002

I am in need of the manual and schematics for the Collins KWS-1 transmitter and associated power supply. I will gladly pay for reasonalbe reproduction and shipping costs.

John C. Lane WA8VEU
2400 Gannon Rd.
Howell MI 48843

I need a manual on the AM 1955A/GRC amplifier-converter which operates on 600-1000 MHz, as well as a manual on the RP-119/GPH signal data reproducer.

Roy W. Johne W9NNM
201 West "A" Street (4)
Iron Mountain MI 49801

I need a little help getting a manual for the Wilson T-1402SM hand-held transceiver. I would also like the sheet on the touchtone pad and the T-15-NC dropin charger.

I will gladly pay all copy costs and postage. I have copying facilities available.

Any help you can give will be very much appreciated as I am dreading the day the radio quits and I have to work on it.

Carl Hattan K0BZU
PSC Box 6752
Patrick AFB FL 32925

I need a schematic and any other information I can get for a Monsanto counter/timer (Model 101-B). I will pay for schematic/manual (or copy) or I can copy and return original. Thank you.

Nicholas Santillo
Box 22, RD 1
Sycamore PA 15364

Does anyone know where I can get my Standard SR-C-145B repaired?

Don Sywassink K7ZIO
4525 Paseo Arruza
Sierra Vista AZ 85635

I need a mixer coil for an HQ-170 Hammarlund receiver—top slug 455 kHz and bottom slug 3035 kHz. I am repairing the receiver for a man with M.S. and any help would be appreciated.

Fig. 1. Sectionalized list of repeaters.

A few years ago, on one of several trips to New Jersey to visit with our children and grandchildren, I found myself with a microphone in one hand, a repeater manual on my lap, and my dear wife, Janet, struggling with a large road map trying to pinpoint the location of Podunk Hollow where there was supposed to be a repeater on .16/.76. "There must be an easier way!" I thought.

Before making the next trip, I made up repeater maps for each state I would be passing through, by marking repeater frequencies directly on the map at their exact locations. In this manner, I could determine whether or not I was within range of the various repeaters and operate accordingly. Two-meter mobile operation then became a real pleasure.

Repeater maps can be made up in several ways using standard-size road maps. Depending on the number of repeaters at a given location, sufficient space on the map can be covered with typist's white correction fluid and, when dry, repeater frequencies can be neatly inscribed on top by hand. A black, felt-tip pen can then be used to provide an outline of the white area to greatly improve visibility. Another method is simply to use

white paper sections cut to size as paste-ons at repeater locations on which frequencies are inscribed.

I recently made up a repeater map of Florida (Fig. 2) which is being distributed by *Florida Skip*, an intrastate, non-profit monthly publication.[1] A handy 11" × 17" size, it is printed on a heavy, pale-green, 60-weight paper. (It was to be displayed in that size as a center-fold spread in *Florida Skip* on much lighter white paper.)

The map was constructed using an 11" × 17" state map put out by auto-rental firms. After a thorough study of the various repeater manuals and the latest Repeater Council listings, a request was made to all trustees to send me up-to-date information about their repeaters as to correct frequencies and location. I then typed a sectionalized list of Florida repeaters (excluding closed repeaters) on 8½" × 11" white bond paper, using a typewriter with a carbon ribbon for good reproduction clarity. (More than one sheet was required to list all the repeaters. Fig. 1 is a reproduction at 69% of its original size.)

The typewritten sheet was then photostatically reduced to 40% of its original size so that the sections could be cut out and pasted directly on the map. After a careful paste-up, a black felt-tip pen was used to outline the white areas. Because blue areas such as the ocean and lakes do not reproduce too well in black and white, the entire state as well as the larger lakes were outlined in black to provide better reproduction.

The repeater listing according to frequency also was typed on 8½" × 11" white bond paper and reduced to 40%. This list has proven to be very useful, especially with the new two-meter rigs with scanning capabilities. After the entire paste-up has been completed, the rest is up to your local printer.

This repeater map has been very enthusiastically received in Florida and probably would be much welcomed in other states. It is indeed a worthwhile project for an active two-meter repeater club. ■

Ten-Meter Lunch Hour

—ham radio for school kids

March has always been a bleak time of year for school kids in northern Michigan. Christmas vacation is long past and Easter break is still several weeks in the dim future. Once the craziness of basketball tournaments is over, there is little to do but study, stare at giant snowdrifts that half-cover the windows, and daydream of spring. Our high-school librarian, in a valiant effort to cheer up a blah faculty and student body with any sort of colorful diversion, was recruiting displays to liven up the big glass cases around the sunken main floor reading room.

I had had a ham radio display the year before that had met with quite a bit of student interest, and I resolved to try again. Along with the usual OSCAR pictures, photos of exotic DX islands, and fancy equipment, I planned to include some simple, low-cost gear that the average ninth- or tenth-grader with a part-time job and a modest budget could realistically afford. From years of experience working with teenagers, I've found that next to problems with the code, the one thing that tends to discourage young people interested in amateur radio is the perceived high cost of the equipment.

Students listening to another school station in Florida. The poster at the left listed license requirements and privileges.

Experienced hams know that it is perfectly possible for a beginner to get on the air for little or no cash outlay, using used or borrowed gear, surplus, or even home-brew rigs (with a little friendly coaching from a more advanced builder), but the school kid just starting out doesn't realize this. He or she sees the ads in the magazines for rigs costing kilobucks—plus riceboxes, kilowatt amplifiers, beams, towers, and elaborate satellite installations. The average kid knows how much money the dealers are asking for fancy CB gear and tends to assume that ham gear, with its greater power, range, and number of "channels," must cost proportionately more.

The display case was prepared with equipment, books, photos, and magazine articles to be changed weekly and new material rotated in for a six weeks period. An attempt was made to include as much simple, home-brew, and low-cost equipment as

Ned Workman, yearbook advisor and old Army radio operator, impresses everybody with high speed CW copy. Since this was taken, he has become KA8KQY.

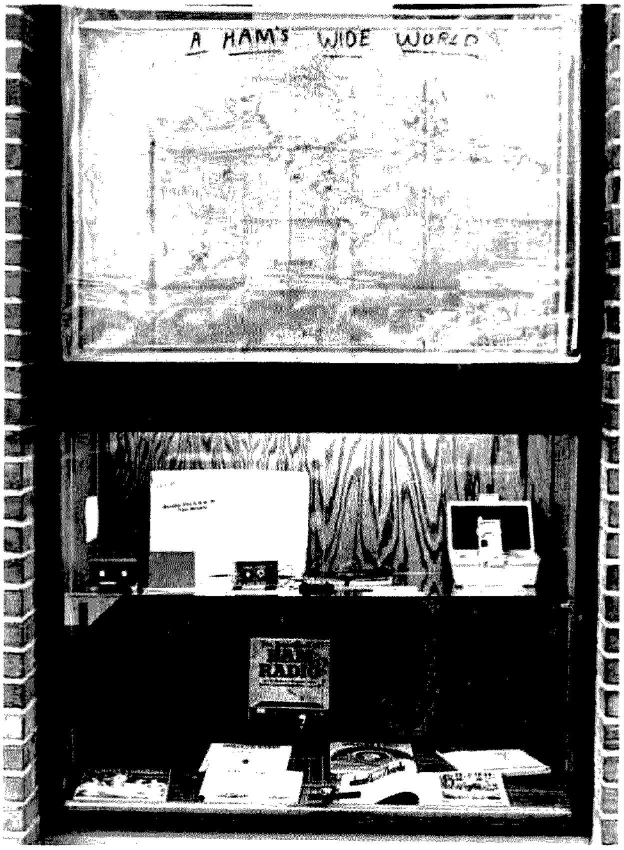
possible. Along with the other gear, a complete Novice station was laid out, consisting of a Heathkit DX-60B, HG-10 vfo, and Lafayette HA-63 receiver.

This display hadn't been in the case for more than a few minutes before requests from students and faculty members began coming in: Why not take the gear out of the glass case and actually put it on the air, perhaps during lunch hour or after school?

I promised to take the matter under consideration and then sat down to think it over. There were some potential problems. I had tried an operating display two years before with the help of a couple of other area amateurs, but with mixed results. Because of severe antenna limitations imposed by the location in the building, we had been limited pretty much to operating with a small vertical antenna on twenty meters. A barefoot transceiver with a less than ideal antenna had left us with a dearth of contacts, especially on phone. The students had enjoyed the display, but the results were less than exciting and hardly seemed to justify the hassle of setting up and stringing long coax runs out of the way of the students who had to be able to use the library during regular school hours.

After considerable thought, I came up with what seemed to be a more practical plan. High-power SSB on the 20- or 15-meter phone bands wasn't the answer. We'd no doubt make contacts, but the whole point of showing what could be accomplished with inexpensive gear and modest power would be spoiled. Daytime in March was just about the peak of the season for 10 meters, and there was more and more low-power AM gear on the air now, thanks to all the CB conversions. An 8-foot vertical could be raised above the surrounding metal-framed buildings and should give good results. The good audio quality of AM would be easier for the students to follow, as many had had trouble with the highly compressed, filtered, and often QRM-blessed voices in the pileups on 20.

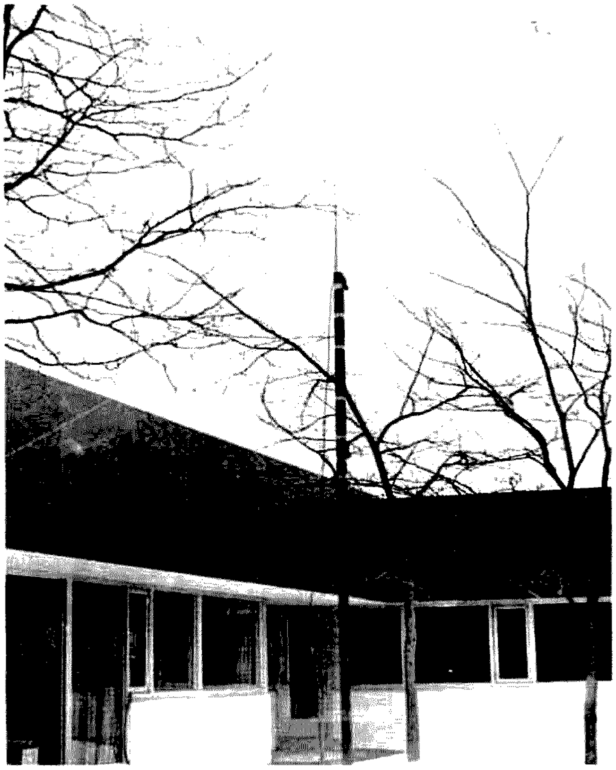
The final installation included the DX-60B and vfo, the Lafayette receiver, an swr bridge, a home-built kit



This display was changed every few days, with an effort to include as much home-brew and low-cost gear as possible. Students marked DX contacts on the world map as they were made.

frequency counter to check up on the calibration and keep us in the band, and a large hi-fi speaker so that class groups could follow the QSOs without straining their ears or having to share earphones. Outside, in the enclosed courtyard that was the only possible antenna site, we raised a makeshift 24-foot T-mast made of 1 × 4 lumber nailed together and painted

Touchy tuning, but that rare DX is still hanging in there.



The antenna. The ground in this inner courtyard was five or six feet below outside ground level.

"Now, where the heck is Victoria, Texas, anyway?"

with the school colors. An 8-foot aluminum tube was the ¼-wave vertical radiator, with three wire radials also serving as guys. With the addition of a piece of wooden dowel, the entire radiating part of the antenna was above roof level, although a three-story metal gym to the south might block some of the best DX.

Since my school preparation period overlapped with the three half-hour lunch periods, I would be able to be in the library over a 90-minute period each day between 1130 and 1300 local time, just about right for the skip to be in on ten.

The first day's operating began with a fifteen-minute dead spot, when there was nothing to be heard on the band but fluorescent lights and the arc welders in the metal shop class down the hall. But a minute or two later, there was a guy in New Mexico calling CQ mobile, his blistering 3-Watt converted CB rig booming in ten over nine; then he was drowned out by several DX stations speaking Spanish, and the fun was on.

In all, we made about two hundred contacts and spent a lot of time eavesdropping on as many more. A couple dozen of these were DX on AM, including Zagreb, Hamburg, the Canal Zone, and several from Great Britain. This is nothing compared to what a serious DX station would do in a contest, of course, but it was felt that a leisurely, rag-chewing approach would be more interesting to the students than just trading signal reports for a QSL. Big world and North American maps were kept posted on the wall and on the operating table, with callsign districts marked off with felt markers on plastic overlays. New states and all DX contacts were marked on the maps with little discs of fluorescent orange paper donated by the librarian.

The high points of student interest were a long (1-hour-plus) rag-chew with another high school student in Florida operating a school station (the W4 flatly refused to believe the nine-foot snowbanks the Michigan kids were describing) and another long visit with a G3 in Lancashire. That particular day, the school was celebrating a 1950s revival for a yearbook benefit dance, and the students were all in bobby sox and Fonzie jackets. The English ham was an old rock-and-roll fan from the 50s, and he kept the kids interested with tales of a recent Bill Haley concert, British rock concerts, and soccer riots. The yearbook advisor amazed everybody by copying high speed CW with his trusty layout pencil; he had to switch to a typewriter for copy over 35 wpm, however!

Overall, the project was a resounding success, though there were minor disappointments. The old receiver, while performing admirably on AM, was too touchy to tune SSB and CW satisfactorily, and much good DX may have been missed as a result. CW was also rather disappointing, although a few contacts on 10 were made, and we loaded up the coax and ground radials with a random-wire antenna tuner and managed to work a few Novices on 40 and 15 meters. The other disappointment was that we were unable to hear any OSCAR passes, although several attempts were made.

On the positive side, everybody's winter blahs were temporarily interrupted, and enough interest was raised so that several students expressed interest in getting a Novice ticket. The community enrichment night school decided to offer a licensing class that spring, with eight or ten people ready to sign up.

I have no doubts but that the project was a worthwhile one, and the library staff agreed—despite the noise and cables strung around the room. All the ham-related materials were checked out from the library and remained in high demand for a long time after the lunch-hour station first went on the air. ■

HAM HELP

I need a schematic and/or manual for a Central Electronics Multiphase rf analyzer, Model MM-2. I will copy and return, all postage paid.

Marvin Moss W4UXJ
Box 28601
Atlanta GA 30328

I need info on modifications, hints, kinks, and improvements which may be used on the Radio Shack Model AX-190 ham-band receiver.

John Dolan KA4OXO
PO Box 651 T.S.
Greenville TN 37743

I am in need of an assembly manual for a Mosley quad, Model MCQ-3B. In particular, I need the length of the wire elements.

William P. Smith K3LF
RD #2
Cold Spring Creamery Rd.
Doylestown PA 18901

I need schematics and manuals (both operating and maintenance) for the following equipment:
1. Alltronics Howard Model "L" teletype converter;
2. Heathkit "Twoer" ("Benton Harbor lunchbox");
3. DEI signal monitor, Model SM-7403;
4. Kleinschmidt TT76 and TT98 teletype equipment.

CORRECTIONS

The TR-9000's microprocessor is *not* the 6500-based chip mentioned in the August, 1981, review. It is a NEC 650C CMOS microprocessor. This 4-bit device features 80 instructions, a 2000-byte × 8-bit read-only memory, and a 94-byte × 4-bit programmable memory. The same chip (with different ROM memory) is used in Kenwood's TR-2400 and TR-7800.

Paul Schmidt K9PS
Crane IN

Several errors crept into the September and October issues of *73*. Here they are:

- K7NZA's article, "That They Might Communicate," on pages 66-69 in the September, 1981, issue, incorrectly refers to J. C. Buckner as a J. C. Betner. Our apologies to Mr. Buckner.
- Contesters, beginners and experienced alike may want to note several corrections for "The Contest Cookbook" which appeared in the October, 1981, issue. The correct Field Day exchanges are:

CW: "K6ZM 1C EB de WB6CEP K"
Phone: "K6ZM one charlie East Bay from WB6CEP, over"

When discussing rest period strategy, author N6OP defined "short contests" as those that are 20 to 30 hours long. This category should also include the mini-contests—even those as short as four hours.

- QSO party enthusiasts will be pleased to know about several new contests that can be added to Table 1 of the article "Controlled Chaos," which appeared in the October, 1981, issue. Alabama holds their event on the fourth weekend in August; out-of-state stations are required to send their state. The second weekend should be reserved for the New Mexico QSO Party. Out-of-state contestants need to relay a serial number and their state.

Changes for Table 1 include the date for the Alabama contest; it's now scheduled for the fourth weekend in August. You can plan on working South Carolina stations the second weekend in March. Finally, the Nebraska square-off has been moved to the fourth weekend of the month listed and Vermont's QSO Party is now on the second weekend of the month listed.

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place.

HICKSVILLE OH
NOV 1

The Defiance County Amateur Radio Club will hold the Defiance County Hamfest and Flea Market on Sunday, November 1, 1981, from 8:00 am to 4:00 pm at the Defiance County Fairgrounds, Hicksville OH. Donations are $1.50 in advance and $2.00 at the gate. There will be free parking, overnight camping (October 31st), and trunk sales space. Doors will be open for setups at 4:00 pm on October 31st, and table space will be available. First prize is a 2m mobile. For hamfest inquiries and table reservations, contact Ed Ballard, Jr., WD8JVV, RR 1, Roland Road, Sherwood OH 43556, or phone (419)-899-4209.

SOUTH GREENSBURG PA
NOV 7

The Foothills ARC will hold its annual swap and shop on Saturday, November 7, 1981, at St. Bruno's Church in South Greensburg PA. Doors will be open from 9:00 am until 3:00 pm. Registration is $2.00 each or 3 for $5.00. All facilities are indoor. Main prize is a Kenwood TS-530S HF rig. First prize is an Icom IC-2A hand-held. Talk-in on 146.07/.67 and 146.52 simplex. For advanced table reservations, phone Chuck Hamman WB3HZM at (412)-837-9194 after 5:00 pm.

SELLERSVILLE PA
NOV 8

The R.F. Hill ARC will hold its 5th annual hamfest on November 8, 1981, in the Sellersville National Guard Armory, Sellersville PA. Doors will open at 7:00 am for sellers and 8:00 am for buyers. There will be a grand prize, door prizes, refreshments, and heat. Talk-in on .28/.88 and .52. For further information, contact R.F. Hill ARC, Box 29, Colmar PA 18915, or Chet Pierson K3TV, Box 336, RFD 1, Greenlane PA 18054.

NORTH HAVEN CT
NOV 8

The Southcentral Connecticut Amateur Radio Association will hold its second annual Electronics Flea Market on Sunday, November 8, 1981, from 10:00 am to 4:00 pm indoors at the North Haven Recreation Center, Linsley Street, North Haven CT. Admission is $1.00; children under 12 will be admitted free when accompanied by an adult. Sellers may set up at 9:00 am; spaces are $5.00. Refreshments will be served and door prizes will be awarded. Talk-in on 146.01/.61 (W1GB). For information about special arrangements for commercial exhibitors or for reservations (make checks payable to SCARA), contact the Southcentral Connecticut Amateur Radio Association, PO Box 81, North Haven CT 06473.

MASSILLON OH
NOV 8

The Massillon ARC will hold its 24th annual auction, Auctionfest '81, on Sunday, November 8, 1981, from 8:00 am to 4:00 pm at the Massillon Knights of Columbus Hall, Cherry Road, Massillon OH. Tickets are $2.50 in advance or $3.00 at the door. The flea market opens at 8:00 am and dealer tables are $3.00 per 8-foot table. The auction, beginning at 11:00 am, will include prizes of a Kenwood TS-130S, a Ten-Tec Argosy 515, and an Icom IC-2AT. Door prizes will be given away hourly. For further information or table reservations, send an SASE to Steve Nevel WD8MIJ, 1864 Massachusetts Avenue SE, Massillon OH 44646.

NEWMARKET ONT CANADA
NOV 14

The York North Amateur Radio Club will hold its fifth annual flea market on Saturday, November 14, 1981, at the Newmarket Community Centre, Newmarket, Ontario. General admission is $1.50, which includes a door prize ticket. Admission for exhibitors is $3.50, which includes a door prize ticket and one table. Additional tables are $2.00 each. The flea market will run from 0800 to 1400 EST, but the doors will be open earlier for exhibitors. Talk-in on 146.52 (VE3YNA) and 147.225/.825 (VE3YRC).

GRAND FORKS ND
NOV 14

The annual FORX ARC Hamfest and Banquet will be held on November 14, 1981, beginning at 9:00 am. The A.V.T.I. and banquet will be at the Ramada Inn. The registration fee for the hamfest is $2.00 and the banquet is $7.50. Talk-in on 146.34/146.94. Contact WBØBNR or KAØHDN, or write WBØBNR, Box 1638, Grand Forks ND 58201.

STONE MOUNTAIN GA
NOV 14-15

The Alford Memorial Radio Club, Inc., will hold its 9th annual Famvention on Saturday and Sunday, November 14-15, 1981, at the Stone Mountain Inn, Stone Mountain GA. Activities include dealer displays and large flea market area. Registration is a $5.00 donation. Talk-in on 146.16/.76 and .52. For further information, contact Carl Nichols K4ZYK, Chairman, 1657 Flicker Drive, Jonesboro GA 30236; phone (404)-478-4515.

FORT WAYNE IN
NOV 15

The Allen County Amateur Radio Technical Society, Inc., will hold the 9th annual Fort Wayne Hamfest on November 15, 1981, from 8:00 am to 4:00 pm at the Allen County Memorial Coliseum, Fort Wayne IN. Admission is $2.50 in advance or $3.00 at the door, with children 11 years old and under admitted free. There will be a large flea market, forums, and door prizes. The Coliseum charges a $1.00 parking fee. Regular tables are $6.00 each and premium tables (on arena perimeter with curtain backdrop, ac power, and personal attention) are $20.00. Talk-in on 146.28/.88. For more information or pre-registration, write Allen County Amateur Radio Technical Society, Inc., Attention: Hamfest Committee, PO Box 10342, Fort Wayne IN 46851.

OAK PARK MI
NOV 29

The Oak Park High School Electronics Club will hold their 12th annual Swap 'n Shop on Sunday, September 29, 1981, from 8:00 am to 4:00 pm at the Oak Park High School, Oak Park MI. There will be door prizes and refreshments. Admission is $1.50 in advance; $2.00 at the door. 8-foot tables are $5.00 in advance; $6.00 at the door. For reservations or more information, send an SASE to Herman Gardner, Oak Park High School, 13701 Oak Park Boulevard, Oak Park MI 48237, or phone (313)-968-2675.

FAIRBAULT MN
DEC 5

The Courage Center Handi-Ham System will hold its annual winter hamfest on Saturday, December 5, 1981, at the Eagles Club, Fairbault MN. There will be a flea market, a dinner at noon, a program, and prizes. For more information, contact Don Franz WØFIT, 1114 Frank Avenue, Albert Lea MN 56007.

HAZEL PARK MI
DEC 6

The 16th annual Hazel Park Amateur Radio Club Swap & Shop will be held on Sunday, December 6, 1981, at Hazel Park High School, Hughes Street at 9½ Mile Road, 1 mile east of I-75, Hazel Park MI. Tickets are $2.00 and tables are 75¢ per foot. Doors will open at 8:00 with the main prize drawing at 2:00 pm. There will be plenty of food and free parking, plus hourly door prizes. Grand prizes are included with the admission ticket. Talk-in on 146.52. For more information, send an SASE to Jack Field W8UPU, 1444 E. Evelyn, Hazel Park MI 48030.

W2NSD/1
NEVER SAY DIE
editorial by Wayne Green

from page 8

strike holding our plane up for connections from the US. We'd avoided the problem in the US by driving to New York for the flight instead of starting from Boston or Manchester, New Hampshire, as we had first planned. Despite the late arrival hour, we were met at the airport by a ham/computer contingent, complete with my ham license and an HT to use with the local repeaters. W2NSD/ZS was on the air!

The next morning, I woke up and opened the curtains of the hotel room...to find myself in the middle of a large city, complete with high-rise buildings. It could have easily been Chicago or Philadelphia. I checked in on the 145.650 repeater and talked with a bunch of well-wishers. In minutes, I was being visited by Julius Lieberman ZS6AF, the local ham store owner and Kenwood dealer. He brought up a 2400 HT, charger, and special cube tap to fit the weird power sockets.

The day started out with an interview with the editor of *Computerweek*, followed by an interview for the local paper. Then I recorded a tape to be played over the ham network on Sunday, since I would be out of town at the time and might not be able to call in on the countrywide net. In fact, I was flying at the time of the net, so the taping was a good precaution.

In the afternoon, I visited ZS6AF's shack and managed to hook W2NSD/ZS up with W2NSD/1 in Peterborough... plus many more contacts around the US and through Europe. Then Sherry and I went on to dinner with a computer group, enjoying a banquet of South African seafood.

With not a lot happening over the weekend, Saturday was the best time to take off for a couple of days of new country visiting. Dave Sommerville, who runs Rand Electronics, had arranged the flight to Swaziland for us. We met our pilot and Cessna at a nearby airport and then spent an hour trying to get the plane started. That wasn't critical in Johannesburg, but what if the plane turned stubborn in Swaziland? The hope was for the battery to charge up during the flight.

It is difficult to build up a lot of confidence in a plane which takes an hour to jump-start, so perhaps we were a bit unsettled when we finally took off from Johannesburg and headed toward Mbabane, the capital of Swaziland. I had my HT in one hand talking with Dave as we left and my camera in the other taking pictures of Johannesburg from the air. I soon was so wrapped up in making contacts through the various repeaters and snapping pictures of the farm country below that I forgot about the plane problems.

When one thinks of Africa, one normally thinks in terms of dense forests, not flat farmland almost identical to our midwest. South Africa is a big country, so they probably have some forests somewhere, but in the triangle I covered during the next two days it was farmland, farms, and small towns...about 800 miles of this.

With 12 million blacks and only 4 million whites, I expected to see some sign of bush-type villages here and there instead of the European (and American) type of settlement. I didn't see anything like that until I crossed over into Swaziland. On the way in, I discovered the Swaziland repeater on 145.650 and contacted 3D6AX, the chap who issues licenses for the country. He told me they had my authorization waiting for me and that it was all okay for me to start signing W2NSD/3D6 as soon as my plane crossed the border. I kept a sharp eye on the flying chart and made him my first 3D6 contact as we went over the border.

Doug Goldman 3D6BG, the proprietor of the Smoky Mountain Hotel, was waiting for us when we landed. Not bad having a hotel owned by a ham...complete with a nice ham station on the premises. That's a lot better than carting a big suitcase full of ham gear 25,000 miles, through customs people, and paying about $5 a pound for overweight now and then. Some countries make you put up a bond on ham gear which is more than the value of the equipment, to make sure you don't accidentally leave it behind when you go.

The hotel is made up of a group of small cottages, with a central building for the bar and restaurant. Not being much of a drinker, I can't say about the bar, but the food at the restaurant was right up there with some of the finest places I've visited. Everything was superb! Doug, who built the place himself and trained all of the help, is looking for a buyer so he can travel and take it easy for a while. Running a hotel anywhere is difficult, but in a small country like this there are special problems...such as no people with any training at all. He had to teach the locals how to garden so he would have fruit and vegetables for the restaurant...and so on.

The night life in Mbabane is at one of the Holiday Inns. There are three of them, with two being right across the road from each other. Two have casinos, so we popped over there to see the action. "The Devil and Miss Jones" was playing...it seems that such pictures are forbidden in South Africa, as is gambling, so the South Africans come to Swaziland for their gambling and dirty movies. I dropped a couple of dollars in the slots and thought that was enough of a donation for the well-being of the country.

The next morning, Doug took us for a tour, showing us the king's palace and the compound next to it where the king lives with his 87 wives and 850 children in small native huts. I got out of the car on a hillside to take a picture of the palace and was hassled by a truck driver who stopped and wanted to know from whom I had gotten permission to take that picture. Well, it's a pretty country, but I really don't need hassles like that.

The king, by the way, has been in business for 70 years... the longest reigning monarch in history. He's still going strong.

With that, we headed for the airport and my flight to Lesotho. I'll go into that a bit next month, along with some pictures of the trip.

DIGITAL TRANSMISSIONS

After all that fuss to get ASCII legitimized, perhaps it is time for the more experimentally minded to get cracking on digital transmissions. The more I think about this...and talk about it...the more enthused I get. But let's move as quickly as we can to 9600 baud (murs?) and not horse around with the slow stuff.

Once we get these systems going, we'll have a corking good emergency system right there waiting for us. The idea for having emergency nets set up with the net control polling the net stations automatically, waiting for any traffic to be sent digitally, is exciting. With this system, we can interface the small pocket computers with our rigs, type in a message and its destination, and the rig will take over when polled by net control, dumping the message at 7300 words per minute...immediately forwarding it automatically to the addressee. We could increase our traffic-handling capabilities by a thousand times or more.

The startup for this, as I mentioned last month, can be with bulletin-board stations which can be accessed over the air. The caller would specify the transmission speed, whether it be 300, 1200, or 9600 baud. The RBB station would then send the menu and wait for the response. This system is developing rapidly via the telephone these days and could just as easily be implemented over the air. Indeed, the gang here at W2NSD/1 is working on a project to put an RBB service on... probably on 14.100 MHz...just above the RT group and below the Canadian phone band.

To recap, the idea of a RBB station is that when you call in, you get a menu. Let's say you pick item #1 from the menu, DX news. Then you would get a list of the currently active rare DX stations, their known operating frequencies and times, operator name, QSL information...and so on. Bulletin boards are two-way devices, so you would be

able to add to the information if you had any good DX news.

#2 might be a status report on the latest FCC news. It might list the dockets up for discussion and the dates of reply, proposed rule changes, and recent FCC rule changes which have been implemented. #3 might be a listing of hamfests and conventions, with the usual information on when, where, how much, who to contact, and so on. #4 could be a list of coming contests, with data on scoring, rules, where to send logs, and so on. #5 could be a place to list your tentative contest scores for comparison after a contest. #6 could be a list of recent certificates announced. #7 could be satellite schedules...and so it goes. At 9600 baud you can offer a lot of service for a lot of users without running out of time.

For the time being, I'd like to encourage all of the experimentation possible, complete with reports and articles in *73* on the results. Without a lot of articles, we are not going to be able to generate the enthusiasm to make this really work. By the time we've published a couple hundred articles, I think we'll start seeing some commercially-made digital gear appearing...and the beginning of a whole new kind of amateur radio.

If you have any problem getting permission from the FCC for experiments, please let me know about it. As far as I know, they've taken the lid off amateur experimenting...a very welcome relief after all these restrictive years...and we are again able to do some experimenting and pioneering.

It took us about five years to get FM and repeaters popular, starting with the *73 Magazine* push in 1969...and the publishing of hundreds of articles, a lot of books, symposiums all around the country, and so on. Perhaps in five years we will see a similar change as a result of digital communications.

HIGH SCHOOLS

As I pointed out to the people in Brazil and South Africa, the electronics technology of any country is directly proportional to the number of hams in that country. This is why Japan is getting so far ahead of us in many technical areas these days. They have over 500,000 amateurs...the great proportion of whom are active. We have a bit over 385,000 hams, of whom perhaps 50% at the most are active. So we have to sit here and choose between Japanese television sets, video recorders, ham transceivers, HTs, calculators, talking clocks, cameras... and so on.

The answer to the situation is for us to get going with more hams. I frankly view this as an emergency situation for America. The FCC can help by providing rules and a licensing situation which will best encourage the entry of new hams. The ARRL can help by getting as many clubs as possible to think in terms of ham growth. We need to get into a 33% growth pattern, not the present 3%... or even the 11% we had in the 1950s and up until the "incentive licensing" disaster.

The best approach I see to getting things going is to bite the bullet as far as our rules are concerned...and then move ahead with our ham clubs and get into every high school in the country and spread the word.

After over 40 years of hamming, and publishing for 30 of those years, I have to admit that I still don't really understand what it is about amateur radio that grabs kids of 14 and 15 years of age. I know that I was excited about the ability to talk with other people...and that working DX was kind of the ultimate thrill in this line. But I've watched thousands of kids be exposed to the same idea and come away bored. What *is* it? I've had it happen in my own shack. A nearby school sent over a batch of students in the right age group. I put on the show, with a few contacts with Europe and Asia...and nine out of the ten kids yawned and retired to another room where it was less noisy. The tenth couldn't be pried away with ice cream.

If we can ever discover what the button is that gets pushed, perhaps we can start pushing that button in all of the high schools.

Why am I stressing the 14-year-olds? Well, most of the studies of ham licenses have shown that about 50% of all newcomers to amateur radio are either 14 or 15 years old. Further, about 90% of these kids are trapped for life, going into electronics or communications later on as a result of their interest. If you read any magazines or newspapers, you know that Japan is way ahead of us in engineers and technicians...and unless we do something about it there will be no catching up. Well, Japan has been pushing ham radio in their high schools for years and it may be no accident that they are now ahead of us in electronics technology.

The Japanese ham magazines run whole sections of pictures of high school club activities. I wrote about this a few months ago and asked for some pictures from our clubs to encourage this type of development. I'm still waiting for the first picture. That tells me something.

Ham clubs can work with high schools to put on amateur radio demonstrations. They can help to set up clubs, with club members coming in to give talks and theory discussions. They can invite the students to come to club member stations to work some DX, RT, and other ham interests. With the present affluence of kids...and the relatively low cost of a ham station...there isn't a lot of demand for club stations any more. When I was a kid, an AM phone station of any power was a very expensive matter. Heck, the cheapest crummiest ham receiver sold for $30 (about $450 in 1981 dollarettes). I had a medium performance receiver and it ran me about $1,350 in today's Monopoly money. Of course, you had to build your transmitter then... there weren't enough hams to make it worthwhile to sell them commercially (we had only 40,000 hams). But even a modulation transformer for a 500-Watt rig cost about $5,000 in today's money. That's why club stations were popular then.

I'll be talking further with the FCC about this situation...and perhaps something can be done to even get a word into the White House about the need for hams as a genuine American emergency. If we do manage to get into another war, we don't want to have to set up defense contracts with Japan for our electronics equipment.

Just as a reminder...perhaps timely in the face of the "plain language rules" which essentially delete any reference to the reasons for amateur radio to exist as a service...one of the basic reasons for amateur radio, as stated in the old rules, had to do with providing a group of trained electronics people for times of emergency. When WWII came along, we had 50,000 hams and 80% of them went into the armed services. Yes, 80%. Many of these hams went right into military training schools to teach civilians the basics of radio and radar. My class at the Radio Materiel School on Treasure Island, as I have mentioned before, had virtually 100% ham instructors...and a bunch of hams in the classes. That was a super school.

Well, we don't have a war coming up...I hope...but we do have economic warfare right now and it is going strong. This is a war that we are losing. We have already fallen so far behind in our electronics troops (engineers and technicians) that even at a 33% growth rate of hams it will take us until 1990 just to catch up to Japan.

AFRICA IN PERSPECTIVE

Having visited a number of African countries...and boned up on most of the rest of them through books, talks with hams who have worked in them, or via letters from hams living in them...I think I have a good grasp of the overall situation. It is not comforting.

In a great many of the countries, you have an educational situation which has no good solution. After generations... hundreds of years...of tribal living, where the women did most of the work and the men hunted now and then, there is a strong resistance to either work or education on the part of the men.

The next problem is one of leadership. With educational levels so low, there is not a lot of communications between people and thus it is relatively easy for a small group to take over a country. Once in power, they have two main objectives...to stay in power and to get as much out of it as quickly as possible. In one country after another, I've seen aid money from other countries going into the Swiss bank accounts of the rulers and their close buddies...with little ever getting to the people. The rulers have no incentive to make long-range plans to help the country be-

cause they know they will not be around to reap the benefits.

This is not a good situation from the ham point of view because if we are going to get hams in these countries, we are going to have to start with relatively well-educated people... and there are very few of these. Then we are going to have to try to interest these few people in amateur radio and spending the time to get further education in electronics... all without any help from the government. Further, a ruling regime really doesn't want a bunch of people who are able to have private communications because that makes it too simple for them to plot to take over the country or to organize terrorist acts.

Those of you who have been reading my editorials for any time know that I'm an optimist and that I try to think in terms of solutions to problems. Well, here's one where I have no solutions. I see all but one or two countries in Africa (out of 57) going downhill... away from civilization. That doesn't provide much of a prospect for the development of amateur radio.

KAHANER REPORT

Larry Kahaner WB2NEL
PO Box 39103
Washington DC 20016

JUST ONE WORD

Like that salesman in the movie "The Graduate," I just want to say one word. No, not plastics.

Deregulation.

It's in the stars for ham radio.

The FCC is on a hands-off kick, not just for amateurs, but for those in all other services: broadcast, common carrier, CB, marine, even business radio. The attitude change was inevitable, and I wish I could say it stemmed from some great karmic enlightenment by the Commission. It didn't. it reflected the FCC's only logical response to rapidly changing technology and, to a lesser extent, a citizenry tired of petty rules.

At one time, conditions forced the FCC to keep a close watch on the airwaves. Unsophisticated radio gear, splattery transmitters, and unselective receivers made everyone's life miserable. Without meaning to do so, communicators and broadcasters continually interfered with each other.

Then came the technology boom. You pulled a switch and talked. You twisted a dial and your receiver picked up only one station, eliminating those around it. Your TV sported automatic fine tuning. All that technology forced the FCC to look at things differently. Not immediately, mind you, but the Commission did finally respond.

For instance, the FCC recently ended the once necessary requirement that a First Class licensee be on hand at a radio or TV station. Unless you're a broadcast engineer who worked like crazy to get his license, you'll have to agree that the ticket really isn't necessary. You turn the station on; you turn the station off. The newer high-technology transmitters rarely go blooey anymore. No need to watch it out of your eye corners. And when major trouble occurs, you call the serviceman. His pocket beeper ferrets him out quickly, even in the deepest, darkest saloon.

The same goes for telephones. AT&T convinced the FCC that no one should be allowed to interconnect any device—such as automatic answerers or speed dialers—to their telephone lines because it would degrade the system. Only Western Electric, Bell's supplier, knew how to build equipment good enough for the sacred network, said AT&T. The FCC bought that argument for quite a while until it finally realized that others could build stuff just as technically sophisticated as Western Electric. It deregulated that part of the common carrier rules now permitting you to connect equipment to your telephone as long as it meets certain specifications.

And while the FCC got comfortable relaxing rules spurred by technology, It embarked on deregulation not necessarily caused by state-of-the-art advances. Radio broadcasters, for example, don't have to adhere anymore to rules which prescribe how much public service time they must air each week or how many commercials they send each hour. It's now up to each station.

Deregulation fever is spreading throughout amateur radio. Several years ago the FCC relaxed rules on log-keeping, mobile identifications, and a few other small items. Everyone seemed to like the changes except some old-timers and, interestingly enough, some just-weaned hams. For reasons only a PhD in sociology understands, these people feel cozy with constrictions and revel in restraints.

No matter; deregulation is in full swing, and a just-released FCC report gives us great insight into where the deregulation future lies for hams.

Now, I'm not much on government reports. Sure, some of them make fun reading, like the GAO studies that show how Congressmen pay two bucks for a haircut because their barbershops are taxpayer subsidized. But this isn't always the case. Most government reports remain dull and dry.

Not so with the FCC report titled "Deregulating Personal and Amateur Radio." It's from the Office of Plans and Policies, the closest thing the FCC has to a think tank. They form projections, raise questions, and suggest innovative, often radical answers to old, crusty problems.

Keep In mind they didn't just issue a "report." That's too banal for OPP. It's officially dubbed a "working paper."

Despite the high-brow moniker, it's written simply, presented so an FCC commissioner can understand it. Although authors Alex Felker and James Brown warn that: "The opinion expressed In this paper is the authors'. They do not necessarily reflect the policies or views of the FCC or any other organization or individual," we know who signs their checks. They're on the same floor as the FCC commissioners.

One of the main points of this 70-page report is that the FCC should eliminate minor rules partly because of new technology, partly because it would encourage new technology.

The paper said: "A number of regulations seem inconsistent with the goals of the amateur radio service. They probably no longer serve any useful purposes either because of technological advances or because they were based in the first place on overly pessimistic predictions of trouble that might arise. Although individually these regulations are not serious constraints to goal achievement, collectively their impact might be significant."

For example, the authors suggested the FCC drop restrictions on automatic repeaters. They indicated that equipment is reliable enough, and the state-of-the-art advanced enough, that any problem—such as a stuck transmitter which so terrifies the FCC—could be handled with little trouble. The present restriction, they said, prevents experimentation with spectrum-efficient techniques such as packet switching, electronic mailboxes, and other digital modes.

One reason the FCC dragged its red-taped feet on allowing hams to send ASCII was that it couldn't monitor transmissions. That argument never held water, the paper suggested, because hams are generally self-regulating, and besides, the FCC hardly listens anyway.

Unfortunately, that same concern still permeates the Commission. When the FCC met earlier this year to discuss whether hams should be allowed to use the new mode known as spread spectrum, Commissioner Abbott Washburn, at first, objected. He said that because the FCC couldn't monitor spread-spectrum transmissions, some hams might operate illegally.

Fortunately, Jim McKinney (who was then Chief of the Field Operations Bureau, now Chief of the Private Radio Bureau) quelled his fears and said hams could be trusted. Subsequently, the Commission Issued a notice of inquiry; comments are welcomed and encouraged.

The report emphasized that

the Commission bears responsibility for slowing technical progress. It stated: "If there is criticism of amateurs from not being more technically advanced, it might be misdirected. Perhaps one should place some responsibility on the regulations, not the licensees. Substantially more regulatory flexibility than the service now has would be desirable."

The report also said that the FCC should relax identification requirements to allow amateurs greater opportunity in using new modes without having to sign on and off in Morse code or voice. Some other suggestions included giving Technicians expanded privileges, establishing a digital license (no Morse code needed), and permitting repeaters below 10 meters. In conclusion, the paper said: "It may be too much to ask that regulation take strong affirmative steps to develop new technologies and other new approaches for personal radio. It is not, however, too much to ask that regulation simply not stand in the way of the new."

The paper recommends that the FCC remember one word. Deregulation.

(Copies of the working paper "Deregulating Personal and Amateur Radio" are available from the Office of Public Affairs, FCC, Room 227, 1919 M St. N.W., Washington DC 20554; (202)-254-7674.)

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

It seems as though interest in RTTY has never been higher. Maybe it's the time of year; maybe the computer revolution has something to do with it. I like to think that this column played a significant role in the introduction of RTTY to hams who might otherwise have missed out on this great mode. This month, I am going to respond to the large number of newcomers who have addressed the question of entry into RTTY, particularly using a computer or video-based terminal.

I have a letter here from Zacharias Liangas, who reads *73* at his home in Thessaloniki, Greece. He is interested in RTTY but has several questions regarding RTTY that help to illustrate some basic points.

Zacharias' first question asks for a definition of RTTY and how that differs from SSTV. I think that the confusion in your mind comes from the fact that both modes are transmitted using similar techniques. But there the similarity ends. To begin with, let's look at RTTY. Radioteletype, abbreviated RTTY, is a method of encoding data describing alphanumeric characters by defining two discrete states of a carrier frequency. Since each character is defined by a number of bits, five in the case of Murray code and eight with ASCII (which we shall discuss later), and each bit may be in one of two states—on or off—so the frequency shift is defined. The on state is termed "mark" and the off state is "space." Arbitrarily at first, and later through legislation, what these exact frequencies may be has been well defined.

Looking at audio frequency shift keying, an audio tone of 2125 Hz is normally used as the mark frequency. During the transmission of one character, the frequency is abruptly changed, in step with the pattern of bits defining that character, to the space frequency. Using the long-standing standard of an 850-Hz shift, or difference between mark and space, this would yield a 2975-Hz tone on space. These days, narrower 170-Hz shift is used; in this case, the space would be 2125 + 170 = 2295 Hz.

I realize that this is a very brief explanation of radioteletype, but the thing to keep in mind is that the carrier frequency changes state *abruptly* from mark to space and back again. This shift is in tune with a bit pattern that defines each character to be sent.

Now, SSTV stands for Slow-Scan Television, and, while it also is sent by frequency shift keying, it is an entirely different animal. A television picture is produced by a scanning beam of electrons sweeping across a cathode ray tube, covering the entire viewing surface in one-thirtieth of a second. The intensity of that beam is modulated in order to produce a picture and the faster the beam travels, the faster the modulation must vary in order to keep up, if you will, with the traveling beam. A faster beam thus requires a higher modulating frequency, and commercial TV signals approach four megahertz in bandwidth requirements.

But, if you slow the scan rate so that it takes, say, several minutes to cover the screen, then you can slow the modulating waveform down accordingly, and with it reduce the bandwidth. That is exactly what SSTV does. By sending one picture every eight minutes, rather than thirty per second, the modulating frequency is reduced to the point where it may be superimposed upon an audio carrier. The carrier is then shifted in frequency in order to encode the level of modulation, much as the RTTY signal is shifted. But here, rather than being only on or off, the frequency may vary anywhere between the mark frequency, here defining a black screen, and space, for white.

Now there are some problems. For example, if you sent an SSTV signal out and used a RTTY signal to modulate the carrier, you would be sending out a form of RTTY in SSTV's clothing. That scheme was described recently in *73* as a permissible way to send ASCII over the air before it was fully authorized. But let's avoid the exceptions and deal with the general case, OK? For the sake of this discussion, RTTY is for sending text to a teleprinter and SSTV sends pictures to a TV monitor. Fig. 1 is an attempt to show the mechanics of this transition in graphic format.

Zacharias' next question relates that several shortwave receivers have a RTTY position on their panels. He wonders what that is for and if it is usable on RTTY. Well, recall that we said that RTTY is sent with audio tones. If you put these audio tones into a well-designed sideband transmitter, what would come out over the air would be an rf carrier, shifting in frequency, exactly analogous to the shifting audio tones. This is called FSK, or frequency shift keying, and requires a beat frequency oscillator (bfo) for reception, just as receiving CW does. That is all that RTTY position means, that there is a bfo present which can supply the missing audio tones. It really says nothing about the stability of the receiver, which is vital to its use on RTTY, and assumes the availability of RTTY receiving equipment, such as a demodulator and printer.

The third question deals with a matter of confusing words, in which confusion Zacharias is not alone. He asks what the difference is, or relationship between, baud and Baudot. Let me deal with the second word first. Baudot is the common name for the five-bit code we use on RTTY. This code is more properly called the Murray code, or even better, the International Telegraph Alphabet No. 2. But Baudot it has been for forty years, and we try to go with the tide.

Baud is an entirely different matter. Data transmission is measured in a speed related to bits per second. That measure, bits per second, is called "baud." In the case of standard ham-version 60-wpm RTTY, that is 45.45 baud. This derived from the length of one data pulse, 22 ms. If one pulse is 22 ms, then there are 1/.022 = 45.45 pulses per second, or baud. Simple, no?

Another newcomer, Avery Comarow W4OGK, from Great Falls, Virginia, writes of his problems with FSK vs. AFSK input to a sideband transmitter. If you look at the spectrum of SSB

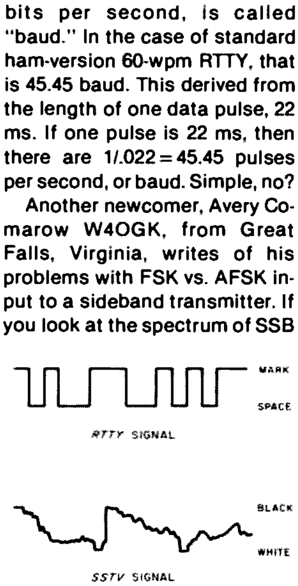

Fig. 1. RTTY vs. SSTV.

transmitters being marketed, you will quickly gain an appreciation of why AFSK is so popular. Many of these rigs either have sealed vfos or have circuits difficult to shift and still maintain stability. That makes a manufacturer of interfacing equipment nervous. So, for such a manufacturer, the most straightforward way to interface with the vast number of rigs out there is to provide a signal that any transmitter can accept—audio. They assume, and you should ensure, that any spurious emissions should be down far enough so as to be legal and not cause trouble.

My advice is that if it is not too much work to directly frequency-shift your transmitter, do it. I think the results are better, and there is less chance of difficulty. By the way, if you do use audio tones, remember to use *lower* sideband to transmit. Audio tones are normally high space, low mark. Using lower sideband reverses this relationship into the common FSK standard low space, high mark. That means that even on twenty, where upper sideband voice prevails, use lower for RTTY.

Avery asks another question which I think the readers of this column might be able to help with. He is looking for objective information on the HAL ST-6000 demodulator. Unable to find any reviews on the TU, he is unwilling to buy it without some impression of the unit. All I can say is that the ST-6000 has a good heritage, through the ST-6 line, and that, examining the manual, it looks like a good demodulator. I certainly would be interested in hearing from users of the ST-6000, pro and con.

A lot of the information covered this month is basic and entry level. The need for more up-to-date material is strong, and there is a new source for this information. Soon the *73* Bookshop section of this magazine will carry the announcement of the *New RTTY Handbook*, about to be published! Containing all kinds of circuits and data, this book covers the gamut of RTTY, from circuit diagrams of machines to computer programs for operating RTTY on the air. Watch for it!

Last December I covered some gift ideas for the RTTYer. I have received quite a few comments on that; watch next month for some more ideas here, in RTTY Loop.

NEW PRODUCTS

DAIWA ANTENNA TUNERS

Daiwa announces two manual antenna tuners for the ham that refuses to compromise on quality!

The CNW-518 is a lightweight, rugged tuner rated at 2.5 kW (PEP), 1 kW CW (50% duty). It will match unbalanced lines from 10 to 250 Ohms impedance and features 80- through 10-meter coverage including the new WARC bands. Attractive styling and planetary gearing provide operating ease and pleasure. Insertion loss is less than .5 dB.

The CNW-418 is rated at 500 Watts (PEP), 200 Watts CW, and incorporates the same features as the CNW-518 except planetary gearing.

Both manual tuners feature the unique Daiwa cross-needle meter that shows forward power, reflected power, and resultant swr at a single glance. Maximize your antenna system performance with these new Daiwa tuners! For more information, contact *MCM Communications, 858 E. Congress Park Drive, Centerville OH 45459*. Reader Service number 479.

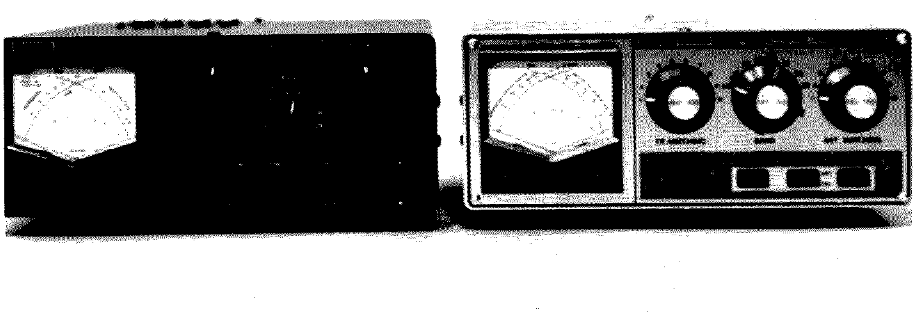
MANHATTAN SOFTWARE'S QSO LOG

Manhattan Software's newest release, QSO LOG, will guarantee a reputation for a phenomenal memory for amateur radio operator users. When the operator hears a callsign on the air, he types it into his TRS-80, and all the details of the last contact with his fellow ham flash onto the screen. Written by a ham/computerist, the program has won high praise from hams who have tested it.

QSO LOG remembers all the details—call, name, QTH, date, time, band, RSTs, and notes on the conversation and the contact's equipment. The 16K version holds 70 QSO records and the 32K version holds 190. The program dumps to tape, loads from tape, and allows on-screen review of all QSO records, updating of contact information, editing, and deletion of entries.

Printout is available, with calls sorted by country and US call area, in notebook format for punching and retaining in a 3-ring binder. A disk version will be available in the near future, with immediate random access to QSOs in a disk file and with a much larger capacity for storing calls and QSOs. The cassette version (16K or 32K) will run on Model I or III and is available through dealers or direct from Manhattan Software.

For more information, contact *Manhattan Software, PO Box 1063, Woodland Hills CA 91365*. Reader Service number 485.



Two manual antenna tuners from Daiwa.

SIMPLE TUNER

Simple Tuner is a RTTY tuning aid that uses an array of LEDs to indicate the presence and the frequency of audio tones. The array is organized in 3 rows and 4 columns, each column indicating a different frequency. The first column indicates 2125 Hz, the second 2295 Hz, the third 2550 Hz, and the fourth indicates 2975 Hz. The top and bottom rows are used to show when the tone is too low or too high, and the center row indicates "just right."

This ability to instantly identify 170-Hz, 425-Hz, and 850-Hz shifts, together with the ability to *see* which way to tune your receiver, makes Simple Tuner a tremendous asset to any RTTY station. With practice, you can usually tell whether the signal is "rightside up" or "upside down." Since hearing the tone is not necessary, deaf hams and those with severe hearing loss can now enjoy RTTY.

Simple Tuner is completely external to your TU and requires only audio from your receiver and a simple +5-V and ±12-V regulated power supply. (If you wish, you can use ±12-V

unregulated if you use Simple Tuner as a standalone unit.) The circuit board measures 5" × 7.5". Simple Tuner is designed to mount directly to the front panel of a cabinet and is compatible with the "SS-20" bus.

After a year of continuous use and having shown this unit to many hams and using their input, we are convinced that Simple Tuner represents a real breakthrough that can benefit anyone active in RTTY. For more information, contact *Inotek Engineering, PO Box 110, Spanish Fork UT 84660*. Reader Service number 478.

CURTIS 8044B KEYER CHIP

Not all Morse operators realize there are two basic types of iambic operation used in modern electronic keyers. Type A, offered by the standard Curtis 8044, does not produce a following alternate element when a squeeze is released during an element (an element is a dot or dash). Type B, employed in keyers from AEA, Ten-Tec, Nye, Heath, and others, does produce a following alternate element after squeeze release. For example, in a type A instrument, squeeze release during the dah in the letter "A" will produce just the "A". In a type B unit, the same action will produce an "R". Similarly, in an "N", squeeze release during the dit produces an "N" with type A and a "K" with type B units.

In order to provide for both user groups, Curtis Electro Devices has designed a new IC called the 8044B (8044BM if the speedmeter function is included). Priced the same as the standard 8044 (and 8044M), the new chip is pin-for-pin compatible and can be used in any existing 8044 socket (or 8043 socket with slight modifications). This is good news for operators who trained on the type B models.

For further information, contact *Curtis Electro Devices, Inc., Box 4090, Mountain View CA 94040, or call (415)-494-7223.* Reader Service number 484.

SHACK DESK FROM RICKER

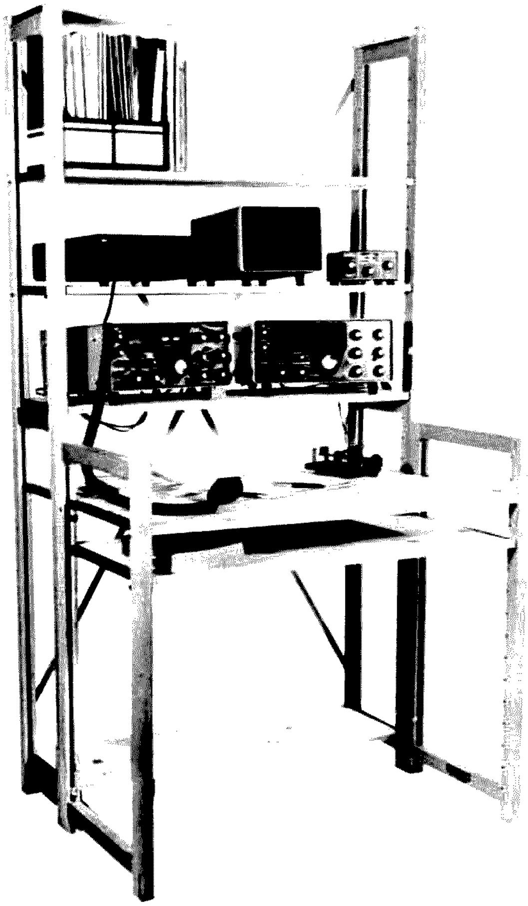
Ricker Equipment, Inc., of Fort Wayne, Indiana, has introduced a new and unique operating desk for use with ham radio equipment and computers called "Shack Desk." It makes use of the space above desktop level more than any other unit on the market.

The Shack Desk is made of wood, with prefabricated uprights and lumber shelves. The shelves are edge-glued, solid lumber designed to carry ham gear weight loads, including linear amplifiers. The standard Shack Desk provides a desktop 30" deep by 36" wide, with 4 shelves above the desktop that are 12" deep and 36" wide. A second 18"-deep shelf 36" wide under the desktop level provides handy storage for reference material. All shelves are vertically adjustable on 2" centers for position, including the desktop level.

The unit is completely open construction at the sides and back for maximum air circulation. Shack Desk offers a fine solution to hams who are working under crowded conditions, making it possible to go up rather than to spread outward.

For hams with plenty of space, the unit is also available 42" wide or in double wide units of 72" or 84". An optional side shelf unit may be attached to the desk with 12"-deep shelves top to bottom. These can be used for additional equipment and/or a technical library. Hams with large equipment will appreciate the unit with deep desktop and shelves—the upper shelves are 18" deep and the desktop is 36" × 36". Shack Desk is sold unfinished with the particular finish left up to the individual user, but it is a simple job to put a finish on any unit.

For further information, contact *Ricker Equipment, Inc., PO Box 12304, Fort Wayne, IN 46863; (219)-745-0825.* Reader Service number 488.



Shack Desk from Ricker Equipment, Inc.

DRAKE ESR24

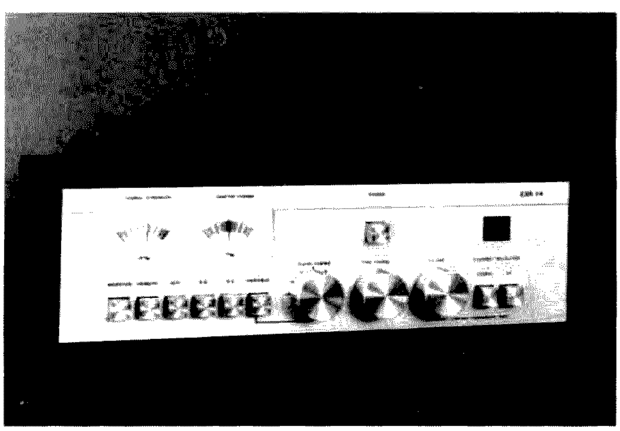
The ESR24 Earth Station Receiver has been introduced by the R.L. Drake Company, Miamisburg, Ohio. This 3.7-4.2 GHz receiver is designed for satellite television reception and features digital channel display, preset and variable audio subcarrier selector, afc for stability, and full metering. For installation versatility, the downconverter module (supplied) may be mounted internally or at the antenna. Accessories for the ESR24 include a remote control, a remote tuning meter, and splash-proof housing. Attractive styling makes the ESR24 suitable for commercial or private installations.

For more information, contact *R.L. Drake Company, 540 Richard Street, Miamisburg OH 45342.* Reader Service number 482.

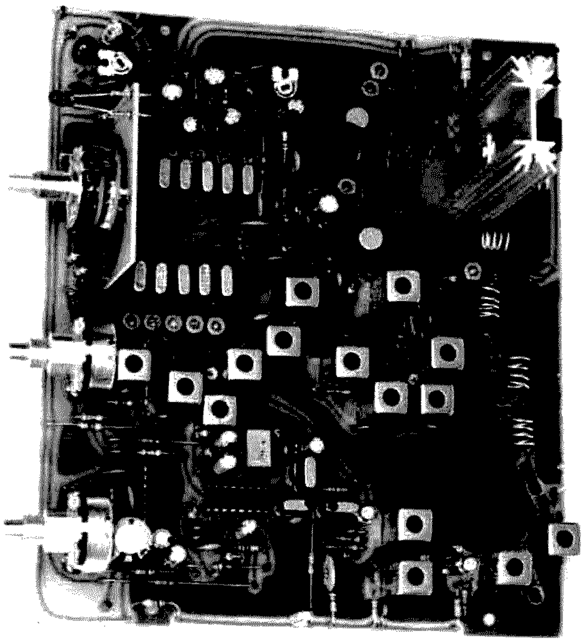
MFJ-1200 CW COMPUTER INTERFACE

The new MFJ-1200 CW Computer Interface converts audio from your receiver to TTL or RS-232 so your computer can "understand" it. It also lets your computer key your transmitter.

When combined with a personal computer and appropriate



ESR24 from R.L. Drake.



Complete Hamtronics VHF FM transceiver all on one PC board.

software, the MFJ-1200 can give you a complete and versatile CW keyboard/reader combination.

For receiving CW, the MFJ-1200 processes the received CW audio from your rig to provide a clean computer-compatible TTL or RS-232 level signal. The MFJ-1200 limits the noise on incoming CW signals, filters it to remove interfering signals, sends the desired signal through a detection stage, post filters the detected signal (this really works to clean out interference), shapes the signal, and finally converts the level of the signal to TTL or RS-232 so your computer can use it.

For transmitting CW, the MFJ-1200 takes keyboard-generated CW at TTL or RS-232 output levels from your computer and drives high-voltage keying circuits to key your tube or solid-state transmitter (−300 V, 10 mA max., +300 V, 100 mA max.).

The MFJ-1200 has 3 red LEDs to indicate tuning, transmit mode, and power on. A reverse/normal switch will invert the output level to the computer if desired. It operates on 6-9 V dc or 110 V ac with the optional MFJ-1309 ac supply.

The all aluminum cabinet is black and eggshell white and measures 6" × 1-3/4" × 3".

The MFJ-1200 is available from *MFJ Enterprises, Inc., PO Box 494, Mississippi State MS 39762*. Reader Service number 483.

New MBA-RO from AEA.

NEW HAMTRONICS VHF FM TRANSCEIVERS

Hamtronics, Inc., well known for high quality FM transmitter, receiver, and power amplifier modules, now has a complete VHF FM transceiver all on one PC board. The new model FM-5 transceiver kit is available for the 6m, 2m, and 220 MHz ham bands and may also be used in some countries on adjacent commercial bands. It operates on up to 5 channels at 10 Watts output. The receiver uses 10 poles of i-f filtering and dual gate MOSFETs for superior selectivity and crossmod rejection.

By mounting all components, including controls and heat sinks, right on the main PC board, construction is simplified and cost is reduced. Cabinets, microphones, and crystals are readily available as options.

For further information, including a 40-page catalog of all Hamtronics kits, contact *Hamtronics, Inc., 65F Moul Rd, Hilton NY 14468, or phone (716)-392-9430.* (For overseas mailing, please send $2.00 or 5 IRCs.) Reader Service number 480.

MBA™ READER ONLY

C. Mike Lamb, President of AEA, Inc., announced that his firm is introducing a reader for Morse, Baudot, and ASCII operation. Designated the MBA-RO (reader only), he said it is a state-of-the-art device using a 32-character vacuum fluorescent alphanumeric display. Lamb said the 32-character display allows for up to five words to be displayed at one time. This extended display is especially useful during high-speed copy.

The equipment features include speed capabilities of up to 99 wpm for CW copy, 60, 67, 75, and 100 wpm for Baudot, and ASCII at 110 and hand-typed 300 baud. The MBA's designer, Dr. Alan Chandler, said the MBA incorporates automatic speed tracking, ensuring no loss of copy due to rapid speed changes in signal reception. He said the MBA requires a 12 V dc external power supply, making it ideally suitable for portable, mobile, or fixed operation.

Lamb said the MBA reader is an ideal training device because it reinforces audio copy with visual copy.

Specifications are subject to change without notice or obligation. For more information, contact *AEA, Inc., PO Box 2160, Bldg O & P—2006 196th SW, Lynnwood WA 98036*. Reader Service number 481.

MMS1 MORSETALKER TALKING CODE TUTOR

Microwave Modules Ltd. has announced a new Morse code tutor, the MMS1 Morsetalker. The Morsetalker is superior to tapes because it offers instruction tailored to an individual or group's specific needs, yet it doesn't require the presence of an instructor. The Morsetalker is a significant departure from earlier tutors in that it features a voice synthesizer which provides talkback of the Morse after transmission, allowing the student to check his copy. Importantly, the Morsetalker sends completely random code groups, eliminating memorization.

Both beginner and expert are provided for with three different character group lengths—one letter, five letters, or fifty letters (in five-character bursts) before talkback. Once the group is sent, the speech synthesizer "speaks" the letters it previously sent in Morse code. For those who no longer require speech talkback, continuous Morse can be sent.

There are six learning levels—letters only: A-F, A-M, A-U, A-Z; numbers only: 0-9; letters and numbers: 0-Z. Morse can be sent at speeds between 2 and 20 wpm. At speeds below 12 wpm, the Morsetalker employs the Farnsworth method, with the characters sent at 12 wpm and lengthened spacing between letters. A high-speed conversion is available that will send at speeds between 12 and 48 wpm.

The MMS1 is housed in a durable diecast enclosure measuring 7-3/8" by 4-3/4" by 2-1/16". Circuitry includes two micropro-

cessors, two memory chips, and a handful of other ICs and semiconductors. Jacks are available for an external speaker, tape recorder, key, and power at 9 to 13.8 volts at 350 mA. For more information, contact *Spectrum International, Inc., PO Box 1084, Concord MA 01742.* Reader Service number 487.

CUBIC ASTRO C HF TRANSCEIVER

A new HF transceiver is available from Cubic Communications. Priced and designed for military and commercial use, it should nevertheless be ideal for DXpeditioners and other hams who demand a lot from their equipment.

The Astro C is fully synthesized and covers 1.8-30.0 MHz in 100-Hz steps. Frequency selection is accomplished by a VRS scanning system similar to that on the Astro 150, keypad entry, computer control, or an accessory remote control. 100 memory channels are available and will store information on frequency, mode, sideband selection, filter bandwidth, and more. Memory channels may be programmed while the radio is in normal operation without disturbing the frequency you are actually operating on. A 24-hour clock is provided, and a lithium battery will keep it and the memories alive independent of external power for 10 years.

Modes available are full or semi break-in CW, SSB, ISB, AM, RTTY, and SSTV. The solid-state finals are rated for a 100% duty cycle and produce one hundred Watts of output in SSB and CW. The receiver includes such amenities as filters for 2.4, 1.8, and .5 kHz, as well as a 6-kHz filter for AM. A tunable notch filter allows rejection of "tuner-uppers." Frequency stability is claimed to be within .0001%, but an external standard can be used for greater stability.

Wherever ham radio takes you, the Astro C should stand up to it. It weighs in at a reasonable 42 pounds and measures 7 inches high by 17 inches wide by 17 inches deep. Operating temperature range is from −30 to 65 degrees C. It will withstand shock and vibration to MIL-STD 810C. It is weatherproof to MIL-STD 108E, and even the front-panel speaker is waterproof.

The Astro C from Cubic.

Pricewise, the Astro C is out of reach for most amateurs, but Cubic is working on a more reasonably priced ham version that retains most of the Astro C's features to be available next Spring. All indications are that Cubic intends to play a prominent role in the ham market, bringing to bear the sophisticated technology used in their military and commercial equipment. For more information, contact *Cubic Communications, 305 Airport Road, Oceanside CA 92054.* Reader Service number 486.

LETTERS

from page 73

that the more things change the more they stay the same... and the beefs don't change either. Tsk. I say balderdash to your sad list of woes.—Wayne.

F.A.R. WINNERS

The Foundation For Amateur Radio has announced the 1981 winners of the eight scholarships which it administers:

- The John W. Gore Memorial Scholarship ($900)—Brian D. Miller KA0DGT, Englewood CO;
- The Richard G. Chichester Memorial Scholarship ($350)—Allyn R. Anderson WB7RVP, Cove OR;
- The QCWA Silent Key Memorial Scholarship ($500)—Stephen Ketler WA1FWA, West Bridgewater MA;
- The QCWA Silent Key Memorial Scholarship ($500)—Gary Myers WA2CUN, Skaneateles NY;
- The Radio Club of America Scholarship ($500)—Carl H. Puckett KA7BWC, Great Falls MT;
- The Edmund B. Redington Memorial Scholarship ($500)—Craig S. Young KA5BOU, Gretna LA;
- The Young Ladies Radio League Scholarship ($300)—Clara L. Muller KA2DYC, Amsterdam NY.

These scholarships were open to all radio amateurs holding at least an FCC General class license or equivalent. This year's applications were received from 29 states, the District of Columbia, and Canada. The Foundation is a nonprofit organization representing forty-nine clubs in Maryland, the District of Columbia, and northern Virginia. It is devoted exclusively to promoting the interest of amateur radio and to the scientific, literary, and educational pursuits that advance the purposes of the Amateur Radio Service.

Information regarding the scholarships to be awarded next year will appear in the April or May issues of the major amateur radio publications.

Hugh A. Turnbull W3ABC
College Park MD

HAM HELP

I wish to express my thanks for putting my request for a power supply and schematic for a AN/PRL9 in your Ham Help section. I was not aware of such a service and I did not request it to be done. I was surprised to get a letter from Bob Bennett, Las Cruces NM, telling me of his power supply for a AN/PRL9. He is going to send me the schematics for it.

Since I'm not a ham, such a help section is very handy to have, especially to me. Again, thanks for your interest.

Dick Howe
Wesleyville PA

MEETING THE CHALLENGE

Referring to the TVRO challenge (page 6, September): Yes, by all means let's get deeper into this interesting part of electronics. Your July issue with the fine story and photos of the Turks & Caicos Island installation of Coops was tops...

Now let's see a flood of TVRO "how to" articles—and while you are at it, how about some 2300 MHz antennas and downconverter construction articles?

Wilbur T. Golson W5CD
Baton Rouge LA

We are ready. How about you?—N8RK.

KL7 SCHOLARSHIPS

The Anchorage Amateur Radio Club is proud to announce that it has established two scholarships—one each at the University of Alaska, Anchorage, and at Anchorage Community College. Each scholarship is for $500/year and will cover tuition and fees for two semesters. The scholarship at UAA is open to all applicants, with preferential consideration going to hams or those active in amateur radio. The one at ACC is likewise unrestricted, although preference will be shown for students in electronics technology.

The club has recently estab-

lished a special scholarship account, with the intent of permanently endowing the scholarship program. At this time, most of the funds come out of the general operating budget of the club. We would like to change that so the interest earned on a special account will cover scholarship costs and have moved toward that objective. While the club members are justly proud of this accomplishment, we would like to invite others to join us in this worthy cause. Any donations received will be placed in the scholarship account and the interest earned from the account will help provide college-level education to young people.

The AARC cordially invites you to join us in this effort. Other clubs might want to help us or even to establish such a scholarship of their own. Individual hams may want to contribute to their local club programs or even to the program here in Anchorage. In any case, the cost is small, but the rewards are great. Contributions may be sent to the address shown below. The club is a tax-exempt organization but cannot accept contributions that are tax deductible.

Imagine having someone in a full and rewarding career who will always remember that radio amateurs helped make that possible.

Steve Norrell KL7IYX
Member, Board of Directors, AARC

Anchorage AK 99504

HAM HELP

I would like to convert a Knight T-60 6-80m transmitter to sideband operation. Any information about this mod would be appreciated. Also, if anyone needs a Knight T-60 manual for his set, he can contact me.

Kevin Neal
Rte. A, Box 221A
Flippin AR 72634

I would like to purchase several 7094 transmitting amplifier tubes or receive information on where they can be purchased.

Tort Isaacson KØHQW
65 Dellbrook Ct.
O'Fallon MO 63366

I would like to get in touch with hams in Salzburg, Austria. Let me know the frequency, GMT, and date to meet you on the air. I am now waiting for my Novice license, and by the time you read this I should have my General class.

I would also like to get in touch with anyone who has made a weather radar receiver and weather satellite receiver, and anyone who has converted a 40-channel SSB CB to 15 meters.

K. C. Walker
Route 3, Box 97
Rocky Mount NC 27801 USA

Help! Help! I need a schematic for an NCX-5. Thanks.

Kay Clausen WH6AGA
73-1161 Mahilani Dr.
Kailua-Kona HI 96740

Although I am not an amateur operator yet, I would be very grateful for any information on the BC-348-Q, an Army Signal Corps receiver that was used during World War II. I am trying to get one of these going after 40 years of inactivity in a musty, wet basement, for use as a first receiver. I am particularly interested in a schematic and in operation instructions. Does anyone know whether any of this information is available? All I know is that these receivers were for sale as surplus after the war from ads in a postwar radio magazine called *Radio News*. As I said, I would appreciate any information or references from anyone familiar with this piece of equipment.

Steven Lapinskas
University of Lowell
PO Box 2029
Lowell MA 08154

I would appreciate any suggestions on how I could remove the glass lens from an automobile headlight in order to use the remaining reflective surface for solar energy experiments. For safety precautions, I broke the vacuum seal located in the back of the headlight.

Marvin Rosen N3BQA
20 W. Madison St.
Baltimore MD 21201
(301)-685-6308

Has anyone converted the "global" program for calculating the distance between your QTH and any city in the world as described in the December, 1977, *73 Magazine* (page 106) for use with the Radio Shack Pocket TRS-80? The Pocket-80 won't handle 2-letter, or letter-numeric (i.e., AB, 2A) string variables, among other things. Any ideas/help will be appreciated.

Gary Payne KE6CZ
1347 E. Dakota
Fresno CA 93704

I am looking for an CU-286/FRR-33 antenna coupler to complete an AN/FRR-33 radio receiving set. Can someone help me?

OSCAR ORBITS

TUNING IN TO OSCAR 8

OSCAR 8 is the only amateur satellite available for everyday communications. Using the satellite for two-way contacts requires a 2-meter signal of about 100 W ERP. This can be achieved either by using a linear amplifier or by erecting a high-gain antenna which is movable in both azimuth and elevation. Such complexities are unnecessary, however, if you simply want to listen to OSCAR 8. In fact, listening to OSCAR 8's 10-meter downlink is a fairly simple procedure and an excellent introduction to the fun of satellite communications. The satellite operates in Mode A (10-meter downlink) on Monday, Tuesday, Thursday, and Friday. The only equipment required is a receiver capable of tuning the high end of the 10-meter band and an omnidirectional antenna or dipole for 10 meters. You will also need some idea of when the satellite is in range. The simple method outlined below will help you determine when to listen for OSCAR 8, and it requires nothing more than a pencil, paper, and a pocket calculator. The method works satisfactorily for all locations in the northern hemisphere.

WHEN AND WHERE

The first step in using the data in the chart of orbital information on this page is to divide a sheet of paper into three columns labeled "Orbit No.," "Time," and "Crossing." Select a day that OSCAR 8 is scheduled to be in Mode A, and write the corresponding orbit number from the chart in your first column. Then get the time and equatorial crossing longitude from the same row of the chart and write them in the second and third columns. You should now have one row of data on your paper, the same data found in the chart for the date you have selected. At this point, you are ready to calculate the equatorial crossing time and longitude for each orbit of the selected day. A pocket calculator will be helpful for this, but even so, the process will be time consuming. We all must make sacrifices in the name of progress!

Now, add 1 to the orbit number and write the result just below the first orbit number. Add 103 minutes (1 hour, 43 minutes) to the original time in row one and write the result in column two of the second row. Finally, add 26 degrees to the longitude in row one and write the result in column three of row two. You should now have two complete rows of data in the homemade table you are constructing. Repeat this procedure, adding 1, 103, and 26 to the most recent numbers in columns one, two, and three until the total in column two exceeds 2400 hours, indicating that you have reached the end of one day's calculations. Whenever the total in column three exceeds 360, simply subtract 360 from the number before writing it into the table. There should be 14 or 15 rows of data in your completed table.

What you have just done is to develop a table showing the orbit number, crossing time, and equatorial crossing longitude for each orbit in the selected day. In essence, you have filled in the gaps in the charts printed in the magazine, which show data for only the first orbit of the day. A new table must be created for each day you plan to listen for OSCAR 8.

We are almost ready to choose a time for listening to OSCAR 8, but you must first determine your longitude. This is easily done by consulting a road map, most of which show longitude and latitude around the perimeter. Now examine your homemade table. Scan the third column, looking for crossing longitudes which are between approximately 10 degrees west of your longitude and 35 degrees east of your longitude. You should find two or three suitable longitudes in your table. When you find them, go across to column two and circle the times corresponding to these longitudes. On the day in question, those are the best times to start listening for OSCAR 8. If you live near the equator, you will begin to hear the satellite a few minutes before the calculated time, while more northerly listeners will hear it after the calculated time.

This is a relatively crude calculation, but it should allow you to hear OSCAR 8 reliably. It is important to remember that the satellite operates on Universal Time (UTC). Thus, when we speak of Monday being a Mode A day, we are referring to Monday UTC, not Monday local time.

WHAT YOU'LL HEAR

The OSCAR 8 10-meter downlink spans the frequency range from 29.400 to 29.500 MHz. A Morse telemetry beacon on 29.400 MHz transmits continuously at 20 wpm, sending coded information about the condition of the satellite. The telemetry consists of several groups of three digits each. Listening for the telemetry beacon is a good way to be sure you are hearing OSCAR 8 and not some other amateur activity on the same frequency.

When the satellite is in range, you will hear many QSOs in progress simultaneously in the 100 kHz that comprises the communications passband. Although satellite users tend to stick to a band plan which calls for CW at one end of the passband and SSB at the other, there is considerable mixing of the modes. OSCAR contacts tend to be short, since the satellite is in range for a maximum of only 20 minutes.

If you have 435-MHz receiving capability, try listening to OSCAR 8's Mode J transponder. Its downlink is 435.100 to 435.200 MHz. Mode J is activated on Saturday, Sunday, Tuesday, and Friday (note that OSCAR 8 is in Modes A and J simultaneously on Tuesday and Friday). The Mode J telemetry beacon can be found at 435.090 MHz.

You may have noticed that Wednesday is not mentioned as either a Mode A or Mode J day. This is because Wednesday is set aside for special experiments and the satellite is not available for normal communications use, although you are welcome to listen to the day's activities.

When listening to OSCAR, you will notice that the frequency of the transmissions from the satellite is constantly changing. This is the famous Doppler shift, caused by the high relative velocity between you and the satellite (thousands of miles per hour!). You will need one hand on the tuning knob almost continuously during an OSCAR 8 pass.

OSCAR represents an exciting opportunity to learn and perfect a new communications technique, and listening will get you started. For more information about amateur satellites, write to the Amateur Satellite Corporation (AMSAT), PO Box 27, Washington DC 20044.—WB8BTH.

ORBITAL INFORMATION

DX Guide *from page 80*

and WAE Contests, two of the major DX events of the summer months.

The most disturbing part of *The Complete Idiot's Guide to DX,* however, is the inclusion of five pages describing the various sorts of turkeys which inhabit our DX bands. Unfortunately, any DXer finds out about these birds soon enough, and there is no reason to spend this much space airing our dirty laundry and unnecessarily discouraging those who haven't yet found out that the gobble of most turkeys is much worse than their bite. A word of warning would be sufficient; Gregg indulges in overkill in his description of "Amateuris Vulgaris."

We have been assured that the second edition of the book, which should be available shortly, tackles most of these problems.

This book doesn't have all the answers. If you're looking for tail-ending techniques or want to know split-frequency tactics, you'll have to find them elsewhere (preferably by listening to how the big guys do it). But if you want to start out in DXing as painlessly as possible and would like to know at least some of the rules before you join the game, *The Complete Idiot's Guide to DX* will be a very worthwhile investment.■

Micronta *from page 92*

you want to measure (dc volts, ac volts, dc current, or resistance—and a few offer ac current scales). Then you need to select the range within that function, and you might have five or more ranges for some functions. Furthermore, you must have the probe polarity correct for dc measurements or the meter will indicate an error, forcing you to reverse your test probes—a nuisance at best.

The new Radio Shack Micronta LCD Auto-Range Digital Multimeter offers many of the newest DMM features in an under-$100 instrument. A single four-position selector knob allows you to measure dc volts, ac volts, resistance, or dc current with a large 3½-digit floating-decimal-point LCD readout. As you make the measurement, the decimal point moves to the proper position, automatically setting the proper range. You can measure up to 1000 volts on dc, 500 volts rms on ac (accurate to about 15 kHz), dc current up to 200 milliamperes, and up to 2 megohms of resistance. If the test probes are connected "backwards" (reversed polarity), the display shows a minus sign, but the actual readings are unaffected. If you go over-range, the display goes blank except for a "1" on the left side.

A range-hold feature, usually only found on more expensive auto-ranging DMMs, allows you to freeze the decimal point location for additional reading within that range. This saves the time normally required for the meter to seek the correct range. The range-hold feature is enabled by moving the on-off switch to the range-hold position when the desired decimal-point location is displayed. This feature works for ac voltage, dc voltage, and resistance measurements. The current-reading display has only one decimal point location (100.0), and so it appears range-hold would be unnecessary. However, if you go over-range (over 199.9 mA), the decimal point disappears when you come back into range, unless you are in the range-hold condition!

A standard 9-volt battery (alkaline is recommended) powers this DMM, and about 8 milliamperes is drawn from the battery when the DMM is on. A subminiature phone jack is provided for a Radio Shack 65-731 or 273-1431 ac adapter ($4.95, 9 volts dc, subminiature phone plug with positive tip). When the adapter is plugged in, the battery is disconnected. A small "BT" on the left side of the display alerts you to a low-battery condition.

On analog meters, an overload could burn out the meter coil or bend the pointer. Also, most analog multimeters need zero adjustments, and many use mirrors behind the pointer to avoid parallax errors in reading. This DMM has effective overload and transient protection and is precalibrated, so no zero adjustments are required. A miniature 1-Amp fuse is built into the battery compartment to protect the DMM if *voltage* is applied to the probes when measuring current or resistance—a no-no!

The DMM is easy to read, since the digits are 3/8" high. There are four digits, but the first digit is either blank or a 1. Therefore, the maximum reading is 1999, making 2000 the over-range condition. On the voltage and resistance function, the display reads .000 when the unit is turned on and the probes are held together. Therefore, you can effectively read .001 volts (1 millivolt) or 1 Ohm (since the Ohms scale display is kilohms and must be mentally multiplied by 1000). When used to measure dc current, the decimal point is stationary at the 100.0 position, so the lowest current resolution is .1 milliamperes (100 microamperes) and the maximum reading is 199.9 milliamperes.

I found the Micronta Auto-Range DMM very easy to use and easy to read, provided you ignore the decimal point excursions as the DMM seeks the proper range. I was disappointed in the lowest voltage range (2 volts) having only a 1-millivolt resolution. Many recent DMMs have a .2-volt scale, allowing readings down to 100 microvolts. Also, since this DMM has only one current range (199.9 milliamperes maximum), you can't use it for measuring either low microamperes or currents higher than 2 Amps. The resistance scale is limited to 2 megohms maximum, in 1-Ohm increments.

Considering that this DMM includes an LCD readout, the auto-ranging and range-lock features, and overload protection for a comparatively low price, it's still an excellent buy for a general-purpose multimeter. For laboratory use, where high precision is required, you might find an instrument with extended lower ranges necessary.

A rugged gray plastic case, 1-1/8" × 8-7/32" × 4-1/8", houses the approximately one-pound unit. A handy feature is the carrying handle, which swivels down to form a tilt-up stand to hold the DMM at a convenient viewing angle. Test leads are included, but the battery is not. The 12-page manual is easy to follow and includes a complete schematic of the unit. Available from any Radio Shack store or participating dealers as Catalog Number 22-196. Reader Service number 476.■

Daiwa *from page 40*

The switchless, tweakless system is even more useful when pruning antennas or adjusting antenna tuners, particularly when using a solid-state transmitter. As you adjust a tuner, swr can jump way above 3:1, causing the transmitter's swr protection circuits to reduce output power dramatically. Using a typical meter, the reflected power would appear to go down, and you could be tuning for high swr rather than low unless you zero the forward meter every time you tweak the tuner. With the Daiwa meters, no matter how much the power output of your rig varies, you are always looking at an accurate measure of swr.

About the only drawback to the Daiwa meters has been their expense, but that stumbling block has now been removed. There are three compact new meters available, and they are considerably less expensive than their predecessors, which are still available. They are less expensive because they are more limited in the frequency range they cover and offer fewer power ranges. In many applications, these limitations won't make any difference. The new models are the CN520, covering 1.8-60 MHz, the CN540, covering 50-150 MHz, and the CN550, covering 144-250 MHz. Each meter offers two power ranges. 200 and 2 kW at full scale with the CN520, and 20 and 200 Watts with the other two meters. A push-button switch located on top of the meter selects the range. SO-239 antenna connectors are provided on the rear panel. The compact trio did well in the realm of basic performance. Run against a Bird wattmeter, all three meters appeared to be well within the 10% margin of accuracy the manufacturer claims. Although their cabinets are plastic, there wasn't any noticeable increase in RFI floating about the shack when one of the meters was put in-line, and we checked 80-10 meters, six meters, two meters, and 220 MHz.

Conclusions

These meters are small! In many installations the small size will be an advantage—a meter can be squeezed into tiny spaces where nothing else will fit. If your taste runs to RG-8/U or RG-213 for interconnecting equipment, take care to fix the meter in place or you'll find it disappearing over the rear edge of your table, pulled by the weight of the coax.

The cross-needle meter approach to measuring swr is clever yet straightforward and represents a noteworthy advance over the all-pervasive switch and tweak boxes currently found in most of our shacks. For more information, contact *MCM Communications, 858 Congress Park Drive, Centerville OH 45459*. Reader Service number 477. ■

P-310X *from page 52*

pedance is a nominal 50 Ohms. Gain of up to 20 dB is possible, controlled by a front-panel knob over a 15-dB range. The 1.8-54-MHz range is spanned in four discrete segments, selected by a front-panel switch: 1.8-4, 4-10, 10-23, and 23-54 MHz, respectively.

I mentioned the bi-linear feature—when you transmit, a special rf sensing circuit automatically connects the transceiver directly to the antenna, bypassing the preamp. At the end of each transmission, the unit switches back to receive with a slight delay, adjustable from 1/2 to 3 seconds by means of a panel control for various operating modes and operator preferences. This feature makes it unnecessary to be concerned with trying to hook into the transceiver's push-to-talk (PTT) or voice-controlled-transmit (VOX) line to cut the preamp in and out when switching from transmit to receive, or vice-versa. An internal four-transistor circuit takes care of the rf sensing, relay energizing, and variable-delay functions. An "off" position on the delay control not only deactivates the preamp, but also serves to bypass it for those occasions when it isn't needed. An LED on the front panel indicates when the preamp is in-line.

I've alluded to the fact that a receiving preamp may not be a necessary investment for everyone. True, most new receivers and transceivers have excellent sensitivity on all bands, at least when they are factory-new. But after a few years, tubes (if employed) may get weak, circuits go out of tune, noise figures go up—slow processes—but so slowly that one may not realize they are occurring. Hooking up the Palomar or a similar preamp to an old tube-type receiver badly in need of alignment and sitting around gathering dust can be an especially amazing experience.

Even with newer transceivers, performance may be marginal on the top two HF bands—10 and 15 meters. Design compromises are always taken in transceivers and will be further exaggerated as the three new WARC bands are designed into transceivers. The preamp should be particularly effective with those transceivers using the pi-network output of the transmitter section as the receiver's rf stage input. Many such units suffer a pronounced drop-off in sensitivity on 15 and 10, much like their older vacuum-tube brethren. The inclusion of six-meter coverage on the Palomar preamp makes it suitable for pepping up a 50-MHz transceiver as well.

I tried the preamp with a Kenwood TS-180S transceiver and an R-1000 communications receiver, which are no slouches in the sensitivity department. The preamp did not noticeably improve reception on 160, 80, or 40 meters, but did help dig down into the noise for weak-signal DX on the higher bands through 10 meters. This was especially true of the TS-180S on 10. The preamp's inherent rf selectivity was helpful on all bands in reducing signal overload from adjacent or out-of-band signals. This characteristic was very helpful when used with the R-1000, whose slow-recovery agc system occasionally gets bombed with strong signals, and the TS-180S, whose front end occasionally lets through a few spurious, image-like signals.

All things considered, the P-310X did a very creditable job in my shack; in transceive operation, the relay was quiet and positive-acting. Had I had available an old clunker transceiver or receiver on which to experiment, results probably would have been even more impressive. Nevertheless, there were a few minor points that warrant consideration by a prospective purchaser.

It's easy to mistune the unit if one isn't careful. This can result in the image or other spurious frequency ranges being boosted, to the detriment of the desired signal. Tune carefully!

There is no attenuator or

provision for use with a second antenna. The former feature would increase the unit's capability to handle cross-mod and overloading effects, while the latter would add flexibility in connecting, say, a general-coverage receiving antenna without need for an external coax switch. Interestingly, the SWL-oriented receiver preamps (models P-305 and P-308) both include these features; each has a switchable 20-dB attenuator and toggle switch used to select either of two antennas.

An extra rf output for a second receiver would be useful, to allow simple connection of, say, a general-coverage communications receiver and a transceiver to enable the preamp to perform double duty. I use both the TS-180S and R-1000 and have to use a coax switch to take care of this chore. Adding an extra output should be a simple project, as the back panel has space for an extra jack or switch.

Despite the few detractors I mentioned, the Palomar transceiver preamp is a good, dependable, and sturdy unit; it's representative of the generally high quality of the company's accessory product line. Too, the attractive aluminum front panel and vinyl-covered metal case add a good deal of "class." The 2½-pound, 8" × 5" × 3" P-310X is available from *Palomar Engineers, Box 455, Escondido CA 92025.* ■

IC-730 *from page 76*

however, has power to spare. An output level pot located inside the rig's bottom cover was readjusted to increase output from 110 to 130 Watts on 20 meters (as read on my Drake W4 wattmeter). By the time this report appears in print, I will have readjusted that pot for an exact 100 Watts output and be enjoying the rig's margin of safety. The rf power control mounted concentric with the mike gain directly varies output independent of mike or speech processor level. SSB operators who enjoy QRP operation can reduce power output while maintaining full audio. The 730 drives both my Drake L4B and home-brew "classic-kilowatt" amplifier (December, 1978, *73 Magazine*, pg. 226) to their usual outputs.

A large final amplifier heat sink is affixed to the 730's rear, and a twist-blade fan moves air diagonally across the sink whenever the 730 is in transmit mode. The super cooling seems like a mild overkill, as the sink has yet to become noticeably warm. The manual explains that high sink temperature will cause a thermal sensor to increase the fan's speed, and also keep it on during receive (evidently after a 20-minute transmission into a 3:1 swr!). A barely perceptible wind noise was noticed and cleared by removing the fan/sink rear cover. The cover's removal also permits more efficient cooling. Swr shutdown checks showed full output until 2.5:1. At 2.7:1 swr, the output dropped to 70 Watts, and at 3:1, output decreased to 55 Watts.

During CW operations, the transmit signal is shifted approximately 400 Hz. I compensate for that shift by turning the RIT control two divisions lower in frequency. This maneuver was initially plotted using a second receiver to monitor both sides of a QSO conducted with the 730.

A key must be plugged into the 730 in order to transmit a carrier. I bypass this requirement during mobile operation with a direct-shorted phone plug in the key jack.

Bells and Whistles

The 730's digitalized dual vfo's are fully microprocessor-controlled, and the vfo's may be operated transceive or used for split operations as desired. A single reprogrammable memory is provided for each band. The memory is also tunable, with memory release-and-recall returning operation to the originally stored frequency. One can thus operate a net and chase DX on both CW and SSB portions of a band at the same time. Pushing the rig's write button (without pushing the memory button) will sync both vfo's on one frequency when needed (such as initially hunting, spotting, and calling a DXpedition upon their "fire-up"). Another button locks tuned frequencies to prevent accidental knob bumps from changing frequency. The tuning knob's tension/drag is also fully adjustable by a screw accessible through a hole in the rig's bottom.

The 730 also features an internal relative power wattmeter (accuracy varies 15 percent of my W4), a very effective speech processor, and an swr bridge. The controls for these units are located beneath an access cover on the rig's top left area. The front-panel meter is thus used to read S-units, alc, rf output, and swr. The "everything-in-one-box" arrangement can't be beat!

Up/down band scanning is possible via an optional microphone. Since I've yet to locate a "scanning mike," I dug into the 730's manual and schematic for details. I had the rig scanning within 10 minutes! The ability to lean back and tune the rig remotely is great, and I'm now planning a keyboard system for entering frequencies directly into the 730's microprocessor.

On the Air

The 730 received its initial checkout during the 1981 Radiosport Contest, and it performed like a DX champ on both CW and SSB. The barefoot rig performed comparably to my TS-120. Switching on the 730's speech compressor added "7 league boots"—and called for reducing rf drive to my amplifier. The increased duty cycle was quite noticeable on the wattmeter, on the amplifier tube plates, and on pileup-cracking ability.

W4CEC and I recently exchanged rigs for a day to evaluate signals. The 730's transmitted signal is quite clean, with ever-so-slightly more high frequency audio response than a TS-820 or 120 (only apparent through direct comparison and knowing the other person's voice). The speech processor adds punch while producing a barely perceptible change in transmitted audio response.

Mobiling with the 730 is sheer pleasure. The quiet receiver and the noise blanker give me the impression I'm in a different auto (my previous rig showed S7 ignition noise; the 730 shows S2 ignition noise).

Conclusion

The Icom 730 is quite a rig for the money. Its numerous features and state-of-the-art technology reinforce my opinion that a new rig is one of today's best dollar values. Icom offers a fairly extensive line of accessories, including matching power supply, external speaker, linear amplifier, and a mobile antenna. For more information, contact *Icom Corporation, 3331 Towerwood Drive, Suite 307, Dallas TX 75234.* ■

HAM HELP

I am Mrs. Ruth Fleischer, wife of former sergeant Martin Fleischer, formerly stationed at Gunter Field, Montgomery, Alabama, serial #32316245, Squadron C-1, 2131 A.A.F. Base Unit.

My husband was in charge of a radio shop at Gunter Field, Pilot School, Basic, and the airplane wash rack was part of this hangar. On or about July 27, 1943, a fire and explosion occurred, trapping the GI occupants (some of the GIs were hams).

In the process of rescuing these men, and amongst the other disabilities received, Martin lost his hearing. Now that he is totally disabled and unable to follow any substantially gainful occupation, he is trying to establish a claim with the Veterans Administration for his deafness.

We are searching for any personnel stationed at Gunter Field, Montgomery, Alabama, between 1942-1945, so that we may discuss the possible recollection of this accident. They may contact me at the address and telephone number below at my expense.

Perhaps in this endeavor to help Martin, we may be able to help the other GIs he rescued and who were also injured. If you need any documentation that I have for verification of these facts, please communicate with me.

Mrs. Ruth Fleischer
2701 East Utopia Road #110
Phoenix AZ 85024
(602)-867-8092

I recently purchased an old Hallicrafters linear amplifier, Model HT 41. I need to get a copy of the schematics and, if possible, operating instructions. If anyone can furnish these, I will gladly pay costs. Thank you.

Glenn Churchill KA2IOI
1 Meadow Rd.
Hudson Falls NY 12839

I need a schematic for a Navy RBH-2 general-coverage system CNA46188 receiver manufactured by National under its own model number NC156-1. I am willing to pay a reasonable amount for the schematic and manual. Thank you.

Terron
9301 SW 4th St., 219
Miami FL 33174

DEALER DIRECTORY

Phoenix AZ

The Southwest's most progressive communications company stocking Kenwood, Icom, Yaesu, MFJ, B&W, Astron, Larsen, Cushcraft, Hy-Gain, Bearcat, and more. Would like to serve you! Power Communications Corp., 1646 West Camelback Rd., Phoenix AZ 85015, 241-Watt.

Culver City CA

Jun's Electronics, 3919 Sepulveda Blvd., Culver City CA 90230, 390-8003. Trades 463-1886 San Diego. Call us for a low quote.

Fontana CA

Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lunar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, landmobile. Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.

San Jose CA
SAN FRANCISCO BAY AREA

Homebrewers' haven; tons of new and used Ham/Computer gear and components. Serving Hams since 1958. We specialize in ICOM, KLM, Mirage, Comptronix. We ship worldwide. Tele-Com Electronics, 15460 Union Avenue, San Jose CA 95124, 377-4479.

San Jose CA

Bay area's newest Amateur Radio store. New & used Amateur Radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santec & many more. Shaver Radio, Inc., 1378 So. Bascom Ave., San Jose CA 95128, 998-1103.

Denver CO

Experimenter's paradise! Electronic and mechanical components for computer people, audio people, hams, robot builders, experimenters. Open six days a week. Gateway Electronics Corp., 2839 W. 44th Ave., Denver CO 80211, 458-5444.

Miami FL

Amateur Radio Center, Inc. "Everything for the Amateur" Since 1960, 2805 N.E. 2nd Avenue, Miami FL 33137, 573-8383, TWX 522035.

Columbus CA

KENWOOD—YAESU—DRAKE

The world's most fantastic amateur showroom! You gotta see it to believe it! Radio Wholesale, 2012 Auburn Avenue, Columbus GA 31606, 561-7000.

Smyrna GA

For your Kenwood, Yaesu, ICOM, Drake and other amateur needs, come to see us. Britt's Two-Way Radio, 2508 N. Atlanta Rd., Smyrna GA 30080, 432-8006.

Preston ID

Ross WB7BYZ, has the Largest Stock of Amateur Gear in the Intermountain West and the Best Prices. Call me for all your ham needs. Ross Distributing, 78 So. State, Preston ID 83263, 852-0830.

Terre Haute IN

Your ham headquarters located in the heart of the midwest. Hoosier Electronics, Inc., #9 Meadows Center, P.O. Box 3300, Terre Haute IN 47803, 238-1456.

Littleton MA

The ham store of N.E. you can rely on. Kenwood, ICOM, Wilson, Yaesu, DenTron, KLM amps, B&W switches & wattmeters, Whistler radar detectors, Bearcat, Regency, antennas by Larsen, Wilson, Hustler, GAM. TEL-COM Inc. Communications & Electronics, 675 Great Rd., Rt. 119, Littleton MA 01460, 486-3040.

Hudson NH

New England's Distributor and Authorized Service Center for all Major Amateur Lines. Tufts Radio Electronics, Inc., 61 Lowell Road, Hudson NH 03051, 883-5005.

Ann Arbor MI

See us for products like Ten-Tec, R. L. Drake, Dentron and many more. Open Monday through Saturday, 0830 to 1730. WB8VGR, WB8UXO, WD8OKN and W8RP behind the counter. Purchase Radio Supply, 327 E. Hoover Ave., Ann Arbor MI 48104, 668-8696.

St. Louis MO

Experimenter's paradise! Electronic and mechanical components for computer people, audio people, hams, robot builders, experimenters. Open six days a week. Gateway Electronics Corp., 8123-25 Page Blvd., St. Louis MO 63130, 427-6116.

Charlotte NC

Santec, Hy-Gain, Cubic Comm., Antenna Specialists, Wilson, W2AU/W2VS, B&W, Pathcom, Nye Viking, Electra, MFJ, Bash, CQ, Arrl., Ameco, Callbook Service, Sales New & Refurbished. Home-Tronics, 1217 Plaza, Charlotte NC 28205, 334-7974.

Somerset NJ

New Jersey's only factory-authorized ICOM and YAESU distributor. Large inventory of new and used specials. Most major brands in stock. Complete service and facilities. Radios Unlimited, 1700 Easton Avenue, P.O. Box 347, Somerset NJ 08873, 469-4599.

Amsterdam NY
UPSTATE NEW YORK

Kenwood, ICOM, Drake, plus many other lines. Amateur Dealer for over 35 years. Adirondack Radio Supply, Inc., 185 West Main Street, Amsterdam NY 12010, 842-8350.

Central NY

Amateur radio hardwood displays made to your specifications—callsigns, plaques, awards or special orders. High quality, fast service, low prices. A.&M. Woodcraft, 313 N. Madison St., P.O. Box 243, Rome NY 13440, 337-5642.

Syracuse–Rome–Utica NY

Featuring: Kenwood, Yaesu, ICOM, Drake, Ten-Tec, Swan, DenTron, Alpha, Robot, MFJ, Tempo, Astron, KLM, Hy Gain, Mosley, Larsen, Cushcraft, Hustler, Mini Products. You won't be disappointed with equipment/service. Radio World, Oneida County Airport-Terminal Building, Oriskany NY 13424, 337-0203.

Columbus OH

The biggest and best Ham Store in the midwest featuring quality Kenwood products with working displays. We sell only the best. Authorized Kenwood Service. Universal Amateur Radio Inc., 1280 Aida Dr., Reynoldsburg (Columbus) OH 43068, 866-4267.

Scranton PA

ICOM, Bird, CushCraft, Beckmen, Fluke, Larsen, Hustler, Antenna Specialists, Astron, Avanti, Belden, W2AU/W2VS, CDE, AEA, Vibroplex, Ham-Key, CES, Amphenol, Sony, Fanon/Courier, B&W, Ameco, Shure. LaRue Electronics, 1112 Grandview St., Scranton PA 18509, 343-2124.

Houston TX

Experimenter's paradise! Electronic and mechanical components for computer people, audio people, hams, robot builders, experimenters. Open six days a week. Gateway Electronics Inc., 8032 Clarkcrest, Houston TX 77063, 978-6575.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

THE FCC ADVISORY COMMITTEE

In order to keep in closer touch with those being regulated, the FCC has established advisory committees, made up of people in the regulated industries, to work with them on needed regulations. In the amateur radio field, this group is the National Industry Advisory Committee, Amateur Radio Service Subcommittee (NIAC). The group has 17 members, of whom about two-thirds normally attend the yearly or twice-yearly meetings.

The most recent meeting was held at the FCC headquarters in Washington with eleven members present. More of the members are interested and influential amateurs than industry representatives, with the only true industry representatives being me from *73*, John Lindholm from *QST*, Chris Imlay from *QST*, and Alan Dorhoffer from *CQ*.

The recent meeting discussed aspects of getting local government cooperation for emergency communications, possible help from MARS stations, and so on. We had been asked for a report on high-speed transmissions for emergency communications and on the possibilities of developing more amateurs for emergency operations. I made the following report, which you may find of interest.

Amateur Radio Emergency Communications: The Future?

At the last NIAC meeting I discussed the matter of the lagging American technology in electronics. Since that time this has been a matter of continued interest in the general media, with articles in *The Wall Street Journal* and several other well-read publications.

It was my concept that much of the explanation for this increasing technology gap lies in the moribund nature of amateur radio in our country. . . particularly as compared with the vital and growing interest in amateur radio in Japan. I felt that this stemmed from the proposed "incentive licensing" rules of 1963, at which time amateur radio in the U.S. stopped its growth for an eleven year period. Indeed, had our ranks continued to grow at the rate at which they had been expanding from World War II until that time, we would have reached our present amateur population in about 1965.

The result of this has been a serious lack of the most precious lifeblood of amateur radio, the 14- and 15-year-old newcomers. Even the spurt of interest in the mid-1970s which resulted from the national enthusiasm for Citizens Band radio brought in more middle-aged recruits than youngsters. Unfortunately, *these* are not the type of amateurs who decide to dedicate their lives to careers in electronics or communications. Thus we have a rapidly aging group of amateurs, with the large part of them well beyond the age when we would expect them to contribute to the advance of American technology. This largely comes from people in their 20s and 30s, not in their 40s and 50s.

One possible solution to the problem would be to encourage the introduction of amateur radio into as many high schools as possible. This is the age recruit which we need. . . which our country needs. Without this group joining our hobby I feel that America can only face further humiliation at the hands of the Japanese engineers and technicans. Further, should any international conflict develop, we will have to be very sure that the next time we have Japan on *our* side. Indeed, if Japan had introduced the no-code ham license in the 1930s it is possible that the war could have turned out differently. We should remember that Hitler publicly regretted his stopping of amateur radio in Germany and ascribed much of the failure of Germany in the war to the resultant loss of technicians

Since we all agree that another international war is unthinkable and impossible, there is no real reason to even worry about our technical people who might be needed in that instance. Still, that does leave us with a gradual falling behind in business as the Japanese, with their army of engineers and technicians, surpass us in calculators, watches, television sets, video recorders, video players and disks, tape recorders, hi-fi systems, amateur radio equipment, *all* communications equipment, telephones, test equipment. . . and so on.

It seems to me that the further we allow ourselves to fall behind in technology, the more we will fall behind economically. I have visited just about every part of the world in recent months and on every front I find the Japanese firms getting ahead of us. Despite the serious problems our Administration is having in trying to cut down on expenses, it may be time for a White House symposium on this critical situation, with some dramatic measures to tackle the problem.

There have been two major technological revolutions in the amateur radio field in the last twenty years. The first was the introduction of single sideband transmissions in the late 50s, which resulted in a change to that mode for virtually all phone shortwave communications on the amateur bands. . . and its use by the military. The second major technology change was the development of the FM transceiver and repeater which came along in the late 60s and developed through the 70s. Since then, despite great leaps ahead in digital and integrated circuit technology by industry, little change can be seen in our ham bands.

The groups of amateurs working for *73 Magazine* are hard at work on a new technology. This will be introduced on twenty meters, probably on 14,100 kHz, as an on-the-air bulletin board. It is our plan to have a radio transceiver system which will automatically answer queries from other stations on that frequency, sending at first a menu of the available material on the bulletin board.

As an example of how this would work, a station would send a call for W2NSD/1 and sign its call. W2NSD/1 would then respond with a list of options of information. Let's say the inquiring station opts for #1, a current DX advisory. W2NSD/1 would then

W2NSD/1 ON-THE-AIR SCHEDULE DECEMBER, 1981

1	80-40 Phone
8	20 RTTY
15	20 Phone
22	40-20 CW
29	20-15 Phone

On both phone and CW nights, look for us in the first 25 kHz of the General portion of each band. On the RTTY night, look for us between 14.090 MHz and 14.100 MHz. We'll be on the higher band first. Sessions run from 7:00 to 10:00 pm eastern time.

WIN WAYNE'S HAM SHACK PRIZE WINNERS

Congratulations to the following lucky winners of ham gear in our recent subscription promotion!

Grand Prize	Carl F. Bogart WA7JWW/WA7OTR Reno NV	FT-901DM, MLA-2500, System 33, rotator
1st Prize	David A. Behar Seattle WA	TS-700A, Hustler Beam, Bird Wattmeter
2nd Prize	Judith A. Posego N9BKQ Lockport IL	TS-820S
3rd Prize	James T. Douglas K3FHC Washington Borough PA	TR-7800
4th Prize	Gerald I. Miles WA4KJK Nashville TN	Realistic DX-300

come on and send all of the latest information on active rare DX stations, including their known frequencies, schedules, QSL information, name of the operator, and so on. At the end of the transmission the inquiring station would have an option of sending unlisted information for possible inclusion on the bulletin board. This would be received at W2NSD/1 and stored for editing by the operator. It then could be added to the #1 list of information.

Number two might be a list of contests during the next few weeks, with scoring information, where to send logs, where to get full details, and so on. Again, further information could be sent to W2NSD/1 at the end of the bulletin transmission.

Plans are to have lists of hamfests and conventions, the latest FCC releases, proposed rule changes, lists of nets and their frequencies, changes in repeater calls or channels, VHF information, RTTY information, SSTV information . . . and so on.

In addition to encouraging the use of advanced digital techniques over the air, these transmissions would be experimental in nature, helping amateurs develop systems capable of communications via ASCII at 300-, 1200-, and 9600-baud speeds. The response of W2NSD/1 would be set to match the calling speed of bulletin board users. 9600 baud can be sent within the confines of an amateur voice channel and, when you consider that this is approximately 8500 words per minute, it is an efficient means of exchanging information.

Let's carry this on to the next step. How does this have anything to do with emergency communications, the basic function of NIAC? Most of the emergency nets of today are on voice and are incredibly inefficient as far as handling volumes of traffic is concerned. Let's look into the future and see where our high-speed automatic digital communications experiment is taking us.

In a few years we may be using small keyboards on which we will be able to type messages. Indeed, these are already on the market, with the Radio Shack TRS-80 pocket computer selling for $230. Let's imagine that instead of just calling a net control station to send a message, the net calls each station in the net in turn and asks if there is any traffic. With digital calling, this polling of a net could be done in milliseconds, not minutes with endless repeating of callsigns. At 8500 words per minute, the net control could call each participating station and ask for traffic in less than a second. If a message has been typed on the pocket computer, the station would automatically dump it over the air when polled. The control station computer would read the address and pass the message along to the addressee instantly. With a network like this it would be possible to handle thousands of times as much traffic as at present with no losses or errors. Further, links with low-band long-range stations could be set up as part of the emergency network. . . even to linking through satellites via microwave transmissions.

This is not a gee-whiz dream of the future. Everything needed has already been invented, so all amateurs have to do is apply the technology we already have developed in the computer field to radio communications. This should be good for amateur radio in that it will generate a new interest in communicating via this new technology. It will be good for industry in that all amateurs will be wanting new equipment. And it will enable amateurs to provide an emergency communications system far beyond anything imagined a year or so ago.

We are taking the first step with W2NSD/1 in the establishment of the radio bulletin board. We will be asking the FCC for permission to experiment with 1200- and 9600-baud transmissions. We will be publishing a vast amount of information on this

Cold Comfort

—an HT to the rescue at fifteen below

One thing was certain. This night would be very cold. As I hunched over my sputtering stove in the fading twilight, melting more snow for drinking water, I wondered how long my HT would continue to perform.

Before I had left on this winter backpacking trip to New Hampshire's White Mountains, friends had told me tales of liquid crystal displays freezing solid, then bursting, at zero degrees Fahrenheit, of fully charged nicads incapable of powering even the receiver portion of an HT at minus ten. Now, at 4:00 pm on this dull and snowy afternoon, the temperature was already minus eight degrees. I knew it would go much lower during the night. The question in my mind was, would the HT quit?

I was hiking alone in these frigid mountains, my only link to the outside world a compact package of imported electronics powered by a pitifully small battery pack. I intended to use my Kenwood 2400 HT to access a two-meter repeater located on a mountaintop eight miles away. In case of trouble, the HT would be my only way of yelling "Mayday."

Suddenly, I was aware of the sounds hanging in the frozen evening air: the roar of my small stove and the sweep of the wind-driven snow. Something was missing. The HT had been quiet for a long time. The reassuring CW ID of the Mount Washington repeater had not broken the squelch for at least half an hour. Preoccupied with stamping out a firm platform in the deep powder snow, setting up my mountain tent, getting the stove going, and making ready for the long night ahead, I had not noticed the HT's silence. Now that silence was overwhelming.

With clumsy, mittened hands I groped through my pack for the HT. I wiped the frost from the LCD readout and was relieved to see it indicating 6.055—the wrong frequency. I had inadvertently depressed the REV button while setting the frequency to 6.655 earlier and was listening on the repeater's input frequency instead of its output frequency. When I restored the switch to the normal position, I caught the tail end of the cheerful CW ID of K1OIQ/R. The repeater was still working and so was my HT. I went back to melting snow and supper preparations as the winter darkness slowly filled my campsite.

This trip had come about as a combination of my interests in winter mountaineering and amateur radio. And, by bringing an HT along, I was able to justify doing something I normally could not justify—making the trip alone. With the HT, I would always be able to reach the outside world and, in the event of trouble, would be able to let someone know where I was. I also thought it would be fun to yack with my fellow hams as I trekked through the Presidential Range in deep winter.

The Presidential Range lies in the White Mountains of northern New Hampshire. This wilderness area provides the most challenging winter hiking and climbing in New England. The region is known for its foul weather and, before the anemometer blew away, the highest wind gust ever recorded on the surface of the planet was clocked at an incredible 231 mph on Mt. Washington's summit. At 6,288 feet, Washington is no giant among mountains. Its reputation as a cruel place in winter, however, is first-hand knowledge to all eastern hikers and climbers who have spent time scuttling across its windswept slopes or scaling the walls of its icy ravines.

My plan was to hike into the national forest south of Mt. Washington, place a high camp at tree line on the Presidential Ridge, spend the night, and then hike down the ridge the following day. I hoped to pass over the summit of Mt. Washington before heading for civilization at Pinkham Notch Camp. I intended to cover a total of thirteen miles in two days, gaining most of my altitude the first day on the four-mile approach up the ridge.

Weather, of course, would play a major role in the success of any plan. The winter of 1980/81 was unusually cold in New England and the weekend I chose for my trip was no exception. I was well aware of the consequences that had befallen those foolhardy enough to be caught high on that exposed ridge in severe winter conditions. Wind-chill factors in excess of −100 degrees were common and, if the weather and winds did not cooperate, my plans would have to change.

I had no success persuading any of my friends to go with me. Perhaps the ominous weather forecasts which predicted snow on Friday night and Saturday with gradual clearing and plunging temperatures on Sunday dissuaded them. In any case, as I hiked along Saturday morning under my fully-loaded, forty-pound Kelty pack, I was glad to be alone. Working my way up through the forest, the only sounds intruding on my solitude were the rhythmic swish of my snowshoes through the powder and the occasional ID of the Mt. Washington repeater.

A Sunday morning self-portrait at fifteen below zero.

The Mount Washington repeater has the widest coverage of any machine in New England. Situated six thousand feet above sea level, it provides reliable communications over a 300-mile, five-state area. Though it shares its mountaintop with TV, FM broadcast, and commercial microwave installations, it has few intermodulation or desense problems.

The machine is privately owned and is open to the public. The only contribution requested from the large number of daily users is good operating practice. The machine is supported by equipment donations from hams in the north country, and maintenance and repairs are carried out by its licensee, Al Oxton K1OIQ and by Bill "Mac" Beal W1PNR. The central role Oxton and Beal play in the machine upkeep and maintenance is the key to its reliability in the harsh mountain environment.

Luckily for the users, both Al and Mac spend considerable amounts of time on the summit of Mt. Washington in the course of their duties as staff members of the Mount Washington Observatory. The Observatory, a non-profit research facility which operates year-round, is rich in folklore and ethereal nocturnal visitors. Rumor has it that at least one ghost is in residence on the summit; on wild nights when the wind is whining, he gives certain Observatory staffers the pleasure of his company. Oxton and Beal are more concerned with repeaters than rumors, however.

Their repeater is a VHF Engineering kit. A scratch-built control system provides tone decoders and interface for the autopatch, audio processing, link to another machine seventy miles away in Concord NH, and auxiliary inputs. Duplexers are by Sinclair and were provided by the Northeast FM Repeater Association. The special Gam half-wave vertical antenna, enclosed in a fiberglass radome, is fed with heliax cable cast off by the neighboring TV station. Transmitter output is 18 Watts, 20 Watts ERP. The repeater is voice-accessed and the trustees encourage users to say nice things when bringing the machine up. The dentist's office "Ahhhhhh" is frowned upon. Normal repeater power is drawn from ac mains, but the machine is capable of running on solar power and has even been run on wind power.

That night there was no shortage of wind for power generation on Mt. Washington. Though it bullied my tent, I was comfortable within the narrow confines of my mummy sleeping bag. Drawn tightly down across my face and around my shoulders, the bag provided a life-sustaining environment. The temperature within the bag was a humid seventy degrees. Four inches away, outside the bag's nylon and fiberfill walls, the temperature was flirting with the bag's minimum comfort rating, fifteen degrees below zero. I had placed two full-length closed-cell foam pads beneath me which provided 1-1/4 inches of insulation from the chilling, hard-packed surface of the snow. While I stayed on the pads, I stayed warm.

In addition to my 6'2" frame, I had managed to stuff a quart of water, the inner liners of my hiking boots, assorted articles of clothing, a bag of GORP (good old raisins and peanuts), my HT, a spare nicad pack, and a headlamp into the bag with me. These carefully chosen items

were the only things that would not be frozen solid in the morning and, as long as I didn't roll over too often, I was totally content.

I had been dozing in the bag for about two hours when the Granite State FM Net was called to order. This public service net handles national and regional traffic in two separate sessions and normally convenes at 7:00 pm on the repeater in Concord NH. Once the net is underway, the Concord and Mt. Washington repeaters are linked, providing coverage of the entire state. For some reason, however, the link was not functioning and, while I could hear the net proceedings from Concord on my HT, I was not able to check in. I wanted to pass a piece of routine traffic to a friend and fellow ham in Bozeman MT who had been a frequent companion on many previous winter trips. Without the link, however, it was doubtful that I would be able to get my traffic through.

Shortly after the net began, net control, N1ALM, briefly left the Concord machine and appeared on the Mt. Washington repeater asking if anyone had outgoing traffic for the net. As I gratefully passed the text of my message to him, we both had to laugh about the propensity we hams have for establishing and maintaining communications between weird locations. Like coral reefs, maximum security prisons, desert ghost towns, or mountainside campsites. Dana's check number matched mine on the first count and while I languished in my sleeping bag, my message began its relay to Montana.

Outside, the weather was deteriorating. The constant swish of built-up snow sliding off my tent and the increasing staccato of the wind did not bode well for the next day's planned route. The exposed ridge, lashed by the northwest wind, would be drifted with new snow making travel laborious and time-consuming. I lay mulling over my plans and reminded myself that the trip was supposed to be fun.

I was almost asleep when the squelch was broken by my own callsign. The gang at W2NSD/1, 100 miles south in Peterborough, was trying to raise me. We had agreed to keep an 8:00 pm sked Saturday evening and at 7:45 pm they were anxiously calling. Most of my fellow staffers were sure I was mad for making the trip in the first place and it was a skeptical and curious group that gathered at the *73* ham shack to hear of my progress.

After assuring them that I was not in a bar somewhere within range of the repeater, I filled them in on what I had been doing since leaving Peterborough. As we spoke to one another across the intervening miles, I imagined their world as it was at that moment: a warm, well-lit, fully-equipped ham shack crowded with friends enjoying themselves. It was very different from the cold, dark world I was in. For a moment, I envied their comfort and comaraderie.

AG1Z was on frequency when I concluded my sked. Willy, an employee of the TV station on the summit of Mt. Washington, volunteered to go next door to the Observatory and get the latest weather forecast for me. It was not good. The forecast called for bitter cold, widely-scattered snow squalls for the next twenty four-hours, and winds gusting to 100 mph. At that moment, it was minus twenty degrees on the summit and winds were gusting to 60 mph. I thanked him, admired his mettle, and then shut down the rig and fell asleep.

Sleep was fragmented and Sunday's dawn came slowly. The orange walls of my tent gradually picked up color as the sun rose behind an icy scrim of fog and blowing snow. I lay awake for a long time in my sleeping bag trying to psych myself up for the inevitable. The hardest part of any winter camping day is leaving a warm sleeping bag and getting into cold clothes, frozen boots, and an icy world. Despite being in my fourteenth hour in my bag, it was easier to lay there pondering the best (and quickest) scenario to follow in getting dressed than to actually get out of the bag and dress.

I snapped on the HT and passed time listening to the idle chatter of other early risers on this frigid New Hampshire Sunday morning. Occasionally, a clipped New England accent would comment on everyone's favorite topic, the weather.

"Ayup Marshall, a might cold here this mahnin. About twenty-five below. Acourse that's on the windy side of the bahn."

As my fellow hams had their second and third cups of coffee, I struggled to get my stove going. Repeated priming finally heated the generator up enough to sustain combustion and soon I too was contemplating the morning's cold over a hot cup of java.

It has snowed heavily during the night and the stubby, frozen shapes here at tree-line were a more appropriate landscape for a hobbit than a ham. The wind-driven snow had sculpted grotesque and beautiful figures during the night as it packed into the scrub growth and pucker brush and fresh drifts covered even the deepest of yesterday's tracks.

Once I was out of my bag, the morning cold kept me moving. Standing in one place for any period of time invited the relentless advance of the cold up through my boots and into my body. To keep warm, I busied myself with breaking camp—a reluctant sleeping bag was forced into its small stuff sack, dirty pots left to freeze were chipped clean of breakfast remnants, and my tent was folded and forced into my pack.

The weather was as forecast. Clouds and blowing snow swirled around me as I wrestled my pack onto my back. As soon as I had it on, the HT I had carefully zipped into a side pocket came alive. N1AHN, a friend I had spoken with the previous day, was calling to check on my progress. John was ten miles away in the village of North Conway. After a short chat with him, I moved off into the storm feeling good that a local was around and interested.

Conditions deteriorated

The winter landscape—more fit for a hobbit than a man.

with each foot of altitude I gained. By the time I was above the last of the scrub, it became obvious to me that I would not be able to continue the traverse. The poor visibility meant that I would be walking compass azimuths on that wild ridge and, should I have to backtrack, would be walking directly into the full force of the wind. Frostbite was a definite possibility and as I stood with my back to the gale, peering down the ridge, I had to remove my metal-frame eyeglasses because they were drawing heat out of my skin so rapidly that my cheeks and temples were losing sensation. My windpants and anorak hood drummed wildly in the wind, and through the tunnel vision of my wool balaclava, I saw a landscape no sane person would inhabit.

I couldn't resist moving a short distance down the ridge and breaking out the HT for a quick test, however. I lifted six distant repeaters from my high point and, as each one came up, I announced that KA1D/portable, Presidential Ridge NH, was listening. Thankfully, no one took the opportunity to chat, and I rapidly retreated toward the relative security below tree line.

While breaking my way down the trail, I managed to raise a friend and let him know of my change in plans. Ken W1NFE was located in Bretton Woods, a small hamlet at the foot of the mountains. We agreed that I would let him know when I was safely back at the trail head. I skied, slid, and slipped the four miles off that ridge thinking of hot showers, hot food, and cold beer. In a few hours, I was down.

The temperature at the trail head was minus fourteen, but it was warm when compared with the cold I'd felt up on the ridge. I flopped my Kelty on the

Swirling clouds and wind-driven snow on the Presidential Ridge.

snow and began fumbling through its labyrinthine pockets for my car keys. As I listened for what I thought would be the final time to the ID of the Mt. Washington repeater, it occurred to me that my Kenwood 2400 HT was one of the more reliable companions I have had the pleasure of hiking with. It didn't freeze up and performed well under less than ideal conditions.

Unfortunately, I was not out of the woods once my hike was over. I twisted the key in the ignition and after a few lethargic turnovers, the engine fired to life. I smugly congratulated myself for the care I had taken in tune-up and battery maintenance while I habitually glanced at the oil pressure gauge. My smugness disappeared when I saw it resting on zero. I anxiously let the engine idle for ten seconds, twenty seconds, a long minute. The gauge never moved. Worse still, the tappets were growing gradually noisier. Apparently, my adventure was just beginning. I shut the engine down and sat in the cab with a sick feeling growing in the pit of my stomach. As I went through the mental gymnastics of what could be wrong, the inside of the windows began to frost up, enclosing me in an icy, translucent cave.

I ruminated on the situation for several minutes when that most noble of human traits, blind optimism, took hold. I simply said to myself, "This can't be happening. I'll just start this thing up and all will be well." So, I did and it wasn't. The oil pressure remained zero while the engine clattered away alarmingly. I admitted to myself that I had a problem.

Sitting in the sub-zero interior of a disabled vehicle thirty miles from the nearest garage with night coming on gets old quickly. The images of hot showers and hot food I had conjured up hours earlier on the trail were still fresh in my mind and I resolved to somehow escape the developing debacle. Then it dawned on me: For the first time in nearly twenty years of hamming, I had—if not an emergency—at least a large bummer on my hands which could be minimized by ham radio. I reached for the mobile rig, but before I could turn it on it occurred to me that I should be using the HT instead. This was the kind of situation I had brought it along for in the first place and it seemed fitting to use it to extricate myself now.

My first call was to W1NFE. Ken was the closest and he answered almost immediately. After I gave him a brief description of my problem, he took the situation in hand. A tow truck was reluctantly dispatched—no small accomplishment on a country Sunday afternoon. The cheapest motel in town was alerted to expect an unexpected guest and a few restaurant recommendations soon followed, too.

To say that the village of Twin Mountain was deserted when the tow truck pulled me in is an understatement of considerable proportion. Besides the garage man and me, only a few scroungy dogs roamed the windswept streets. Nothing could be done for the van that night, so I hoofed off toward the motel that Ken had suggested. One other guest was in residence, he too a victim of car trouble. After we commiserated briefly, I made a few phone calls to find all the area restaurants closed. I then went upstairs to settle into the stillness of my room, littering it with layers of damp clothes and thawing wool knee socks while I munched on the remnants of my trail lunch. Then I headed for the shower.

Sitting on the edge of the bed afterwards, flushed with the warmth of a very long shower, I resigned myself to an early and uneventful evening. I lavishly kicked the room's thermostat up another notch and stretched out on the bed waiting for something tolerable to appear on the only channel the rabbit-eared TV would receive. To my amazement, the phone rang.

W1NFE had tracked me down and was calling to invite me to share dinner and spend the evening with him and his family. At that moment, the world suddenly looked brighter. Ken soon arrived and we headed out to dinner in the twenty-below night, listening to the familiar voices on the Mt. Washington repeater. ■

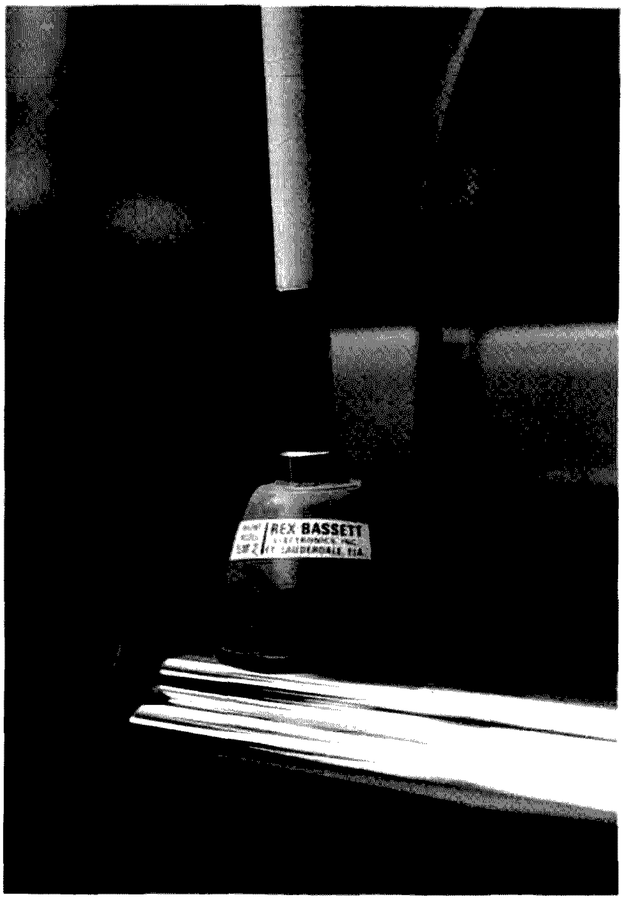
The Rex Bassett TLM-2 Mobile Mount

—banish your fear of flying



The Rex Bassett TLM-2 mobile mount, with a VAC-20 antenna.

HF mobile operation is near and dear to my heart, and I am always in search of better ways to cope with the necessarily large and bulky equipment. One of the biggest problems seems to be mounting the antenna. Whether you use the ubiquitous Hustler system, the Rex Bassett antennas, or motorized wonders like Cubic's, you need something to mount it on that will support the considerable load the antenna presents while motoring down the highway. The mounts offered by the manufacturers are rarely confidence-inspiring. Mechanical integrity and protection of the coax connection are the primary areas that need attention.

The TLM-2 mount from Rex Bassett solves the problems in both areas, as long as your antenna fits a standard 3/8-24 mount. Best of all, it doesn't require a band around the bumper (which won't fit many small cars). The mount resembles an inverted teacup, with a thick gray finish applied. All hardware exposed to the elements is stainless steel. On the bottom of the mount is a threaded SO-239 connector. A single hole is drilled through the bumper or rear deck, and the mount is screwed down with hefty hardware and a thick rubber washer. Once installed, this mount isn't going anywhere—it's rock solid! The SO-239 connector on the other side of the mounting surface is also an important advance. If you mount the antenna on the rear deck of your car, problems with water-logged coax are a thing of the past. Installed on the bumper, the coax will need some sort of protection from the elements. I have used Coax-Seal (available at most dealers) with great success.

Rex Bassett's antenna products have acquired a reputation for intelligent design and rugged durability. The TLM-2 mount continues that tradition. For more information, contact *Rex Bassett Electronics, Inc., 1633 N.E. 14th Avenue, Fort Lauderdale FL 33305.* Reader Service number 476.■

Update Your CW Music Keyboard

—play it again, Sam

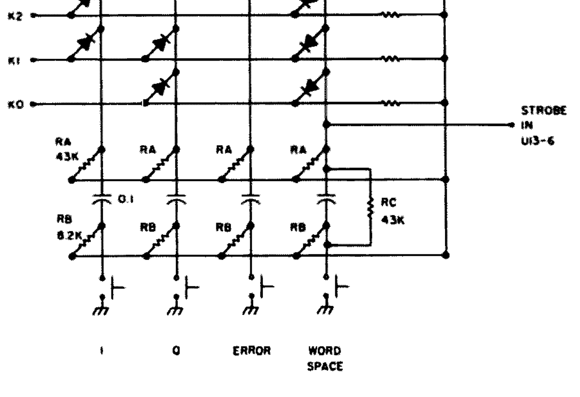

Fig. 1. Wiring diagram for modified diode matrix. R_A and R_B values are not critical; however, a large deviation will cause erratic operation. R_C prevents truncated characters should other keys be struck while the space bar is down. Resistors—¼ W; diodes—1N914/1N4148; capacitors—0.1 disc.

Considering operational features versus IC count, cost, and ease of construction, the Morse keyboard designed by Crom WB9WRE is one of the best keyboard bargains available (*73 Magazine*, February, 1979, p. 84). The author suggests several options, and the design readily accommodates others. One such option, to make typing easier, is described in this article.

I found the basic keyboard awkward to operate because of the key-interlock feature which disables all other keys while one is depressed. Although other keys may be struck, nothing will come out—and that was my problem: striking the next key too soon resulted in omitted characters.

The answer is n-key rollover. With n-key rollover, second, third, etc., keys may be struck while the first and/or succeeding keys are still held down, yet code will go out in perfect sequence (the capability exceeds the demand).

The technique used by Horowitz W1HFA for his Compucoder (*QST*, June, 1975), two resistors and one capacitor in each keyswitch lead, was adapted for this modification, as shown in Fig. 1. Essentially, the functional difference between the original WB9WRE diode matrix and the modified one is the duration of the key-switch input. The static, or rest, condition of data buses K0-K7 and the strobe input is high in both cases. When a key is struck, diodes in the key-switch line take selected data buses low to form the 8-bit binary code representing the character keyed. One or more of the low data buses take the strobe input

low, firing the strobe which loads the FIFO.

The work of the keyswitch is now complete. In the original version, the keyswitch provides a direct ground which retains the 8-bit code on the data buses and holds the strobe input low, preventing reset until the key is released. Conversely, there is no direct ground path in the modified version. The keyswitch discharges the capacitor, sending a negative-going pulse to form the 8-bit code and trigger the strobe. When the negative-going pulse is complete, the data buses and the strobe input revert to the static (high) state and are ready for the next keystroke. The depressed key is inert until released; after release, the capacitor recharges and the key may be used again (there is no discernible delay).

Foolproof key debouncing is a bonus feature of this modification. The keyswitch panels I used were removed from old computer terminals that had individual magnetic reed-switch modules mounted on rails. Some of the switches, outwardly identical to all others but used for special or dual functions, caused sporadic character iterations. I tried numerous strobe pulse widths, and even a 555 wired as a one-shot, without result. A partial cure, effective for some but not for all of the aberrant keys, was finally achieved using capacitor conditioning on the strobe-input line. These keying anomalies completely disappeared after the keyboard was modified.

With due respect to WB9WRE, it's a matter of opinion whether his—or any other—keyboard makes CW music; some would say that only a bug in the hands of an expert can do that! Music or not, this keyboard will play a better tune after this simple modification.■

Photo A. Aluminum angle stock bolted to the sides supports aluminum top, bottom, and rear panels. The top was painted with epoxy spray enamel; clear epoxy protects the transfer lettering on the keys and controls. The digital display is for the QRQ, QRS digital speed indicator. (See article by W7BBX, 73 Magazine, June, 1980, p. 50).

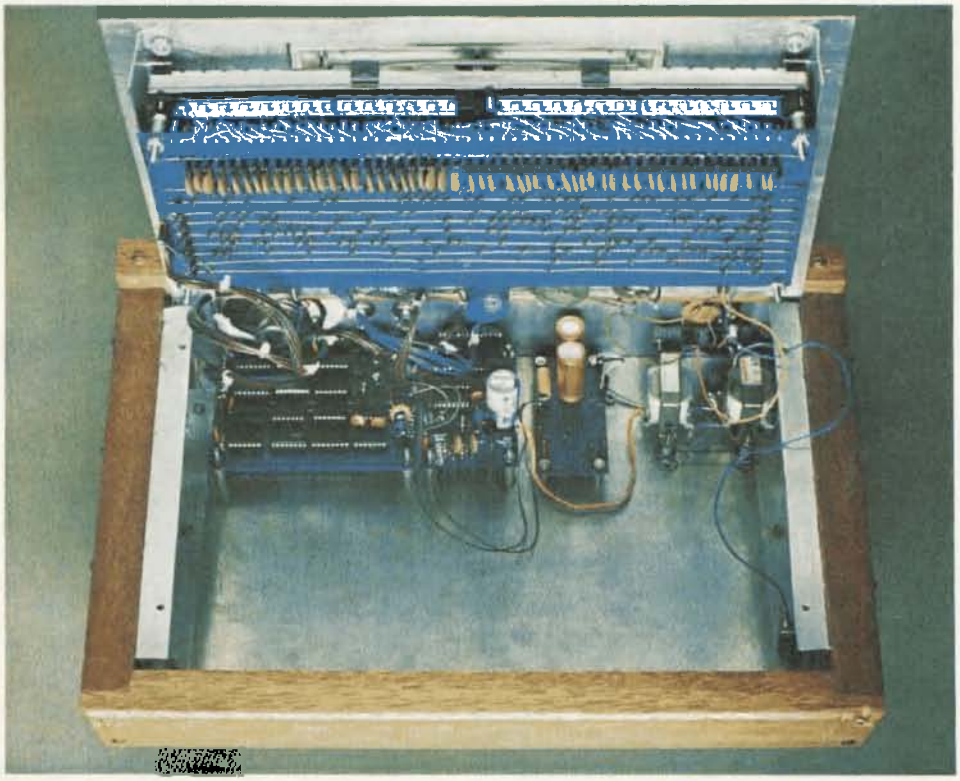

Photo B. The n-key rollover components are at the top of the diode matrix. Vector T-44 Miniwrap posts are used to support the data buses and to terminate keyswitch leads. The keyboard logic, speed meter, and regulator boards are below. All interconnections are made with single row headers.

The Kenwood TR-7730 Transceiver

—let's get small!

Time was, if you had a small car and wanted to put a synthesized two-meter rig in it, you either cultivated a sadistic disregard for your passenger's knees or got yourself one of the two rigs on the market with a compact separate control head. The new Kenwood TR-7730 is part of a trend that will change all that. Measuring a mere 2″ high, 5.75″ wide, and 7.75″ deep, it will fit in the smallest of cars without usurping precious legroom and is even compact enough to fit in the extra radio slot located in the console of many newer cars. One might suppose that a great deal was sacrificed to cram everything into such a small package. Surprisingly, this is not the case. Without further ado, let's take a tour of what the TR-7730 has to offer.

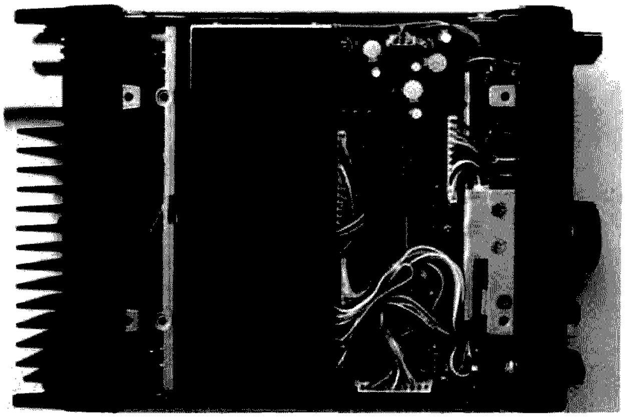
The Features

Starting in the upper left-hand corner of the front panel, we find the memory channel selector and two square push-buttons—one marked "M" and the other marked "MR". The "M" button loads the frequency shown on the digital display into one of the five memories. This frequency can later be recalled by pressing the "MR" button and choosing the desired position on the rotary selector. On memories 1-4, the transmitter offset is set with the switch on the far right-hand side of the front panel. Memory 5 programs both transmit and receive frequencies, allowing access to repeaters using non-standard splits.

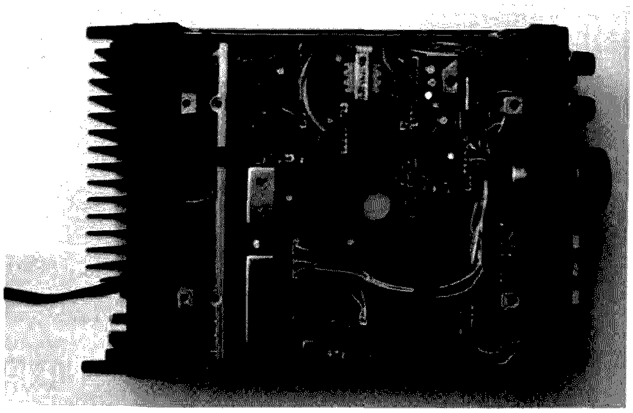
Beneath the memory controls are the combination power switch and volume control and the squelch. Directly to the right of these is the main tuning knob, which steps through the band in a similar manner to the knob on the TR-9000.

Just to the right of the main tuning knob is a switch which selects either 5- or 10-kHz steps with each click of the main tuning knob, a high/low power selector, and an on/off switch for a user-installed CTCSS encoder. Directly above these are three switches associated with the scanning circuitry. Pressing the "Scan" switch starts the 7730 scanning up the band. It will stop on any signal that breaks the squelch and resume scanning when the signal drops. If you hold down the scan button continuously, the rig scans at twice the normal rate. If you wish to remain on a frequency, press the PTT switch on the mike or the "Hold" button on the front panel. Pressing the "MS" switch scans the five frequencies programmed into

The Kenwood TR-7730.



Top view of the Kenwood TR-7730.



Bottom view of the Kenwood TR-7730.

the memories. The scan and hold switches work in both the band- and memory-scanning modes. The up/down switches on the microphone function only in the band-scanning mode.

All displays are of the LED variety. There is a bar-graph S/rf-meter similiar to that on the TR-7800, although the display on the TR-7730 seems to be less prone to flickering. Above this are three LEDs. The one on the far right lights to indicate that a repeater offset has been selected, the middle when the unit is transmitting, and the left when a signal that breaks the squelch is present. To the left of this is the main frequency display.

Most of the rear panel is dedicated to a heat sink for the final amplifier. In a cluster on the left side are the antenna connector, power cable, speaker jack, and a three-prong jack for a memory backup power supply.

Big Rig Performance

Kenwood wisely avoided compromise in the rf stages in their down-sized rig. The transmitter and receiver stages are strikingly similar to those in the TR-7800. Space was saved by shrinking the control circuitry, replacing some discrete components in the audio chain with ICs, and simplifying the final stage. Specifications are virtually identical for the two rigs. Sensitivity is rated at better than .5 uV for 30 dB S/N. Selectivity is spec'd at 12 kHz at 6 dB down and 25 kHz at the −60-dB point. In the high-power mode, our unit exceeded its rated 25 Watts at all frequencies between 144 and 148 MHz. Output in the low-power position is continuously adjustable, making it easy to match the rig to amplifiers requiring only 10 Watts or so of drive. As with most commercial rigs, the deviation level was set slightly high for the close-talking most hams use to improve signal to noise in a car, but was easily readjusted.

In actual use, the TR-7730 is a champ. It worked perfectly the moment it came out of the box. Both transmit and receive audio have the usual Kenwood characteristics—high fidelity with no sacrifice of intelligibility. The squelch is extremely sensitive and seems to latch up resolutely, without the mushiness encountered on many rigs. The controls are thoughtfully shaped and located—most of us should have *no* trouble putting the TR-7730 through its paces in a dark moving vehicle. The bar-graph S-meter, which first struck me as being a gimmick of questionable utility, turned out to be extremely useful. It's a lot easier to read at a glance than a D'Arsonval movement.

The only thing more enjoyable than using this rig is deciding where to install it! It's so small that the possibilities are almost endless. After considerable debate, I removed the AM radio from my Dodge Colt's dashboard and cut away the plastic faceplate with a fine-toothed saw and a couple of files. I didn't know whether or not the rig would actually fit until the faceplate was completely cut away. Behind the dash I found two metal braces, offering plenty of support. The fit is so tight that I didn't have to screw the rig down. I connected the remote speaker jack to the in-dash speakers supplied with the car.

Not for the squeamish, an in-dash or console installation can nevertheless be extremely satisfying. I used to enjoy having my car look like a mobile NASA control center, with rigs hanging everywhere, but I get even more pleasure from the clean setup I now have. If you decide to try an in-dash installation, just be sure that there is plenty of air circulation available. Inadequate cooling can kill a rig.

I used the Kenwood MC-46 DTMF mike, and I must admit I have a love/hate relationship with it. On the plus side, it has all 16 tones, which is useful, and the audio quality of the condensor mike element is unquestionably superior to the mike packed with the rig. On the negative side of the ledger, the mike is small! It took me a couple of days to learn how to handles it without inadvertently pushing one of the buttons on the pad. The hang-up hook resembles those on other microphones I own, but it is slightly smaller, so it won't stay put in either of the mike holders in my car. The small size no longer bothers me, but I am still looking for something to hang the mike on when I am not using it. My advice is to check out the mike carefully before buying, and if it seems too small to cope with, pick up a Kenwood MC-45. You'll need to rewire the mike connector, but the 45 is a solid, full-sized microphone, sure to please the most ham-handed ham! The MC-46 has some nice features, though, and is probably well worth the effort required to get used to it.

Nothing is perfect, of course, and the TR-7730 is *no exception*. I found three relatively minor things I would like to see improved. First, the main frequency display is anything but easy to read. No doubt the location I chose for the rig

Joe Ham: The Consumer

—do you fit the mold?

In spinning the dial across the various amateur bands, it is not unusual to find a QSO concerning radio equipment. A typical QSO might be as follows:

" I am running a Satellite TS6 with a Pacific Kilowatt 2 linear amplifier. My antenna consists of stacked verticals, 33 elements, up about 100 feet. I also have a Demosthenes speech processor . . ."

It appears that there is much interest in the types of radios and accessories being used as well as the reason for purchasing specific radio products. Although there have been many formal studies concerning consumer behavior, the radio amateur as a consumer has been neglected.

The purpose of this article is to present some exploratory research findings on the influence of consumer behavior on the buying habits of radio amateurs.

Methodology

The data in this study were gathered from questionnaires sent to 300 radio amateurs in each of the ten United States call areas. The amateurs were selected by random sample from the *1980 Radio Amateur Callbook*. The sample included amateurs from each of the fifty states, divided into three license class classifications—General, Advanced, and Extra. Two amateurs were taken from each class for each state. The study was primarily limited to HF SSB radio equipment.

The HF SSB Radio

An important part of the study dealt with the types of HF SSB radios owned by the radio amateur, age of radio, where purchased, and purchasing influences. The following is a list of HF SSB radios, including manufacturer and model number, that were most fre-

Purchased	Number of Amateurs (%)
1 year (or less)	23
2 years	20
3 years	14
4 years	10
5 years (or more)	33
Total	100

Table 1. HF SSB radios—when purchased.

Source of Purchase	Number of Amateurs (%)
Local Franchised Dealer	52
Mail-order	32
Another amateur	10
Other (includes factory, swap meet, hamfest)	6
Total	100

Table 2. Where radios were purchased.

Reasons for Purchase	Number of Amateurs (%)
Reputation of dealer (including service)	40
Price	44
Store personnel	10
Other (includes availability, location of dealer, etc.	6
Total	100

Table 3. Reasons for purchasing radio from dealer, etc.

Reasons for Purchase	Number of Amateurs (%)
Reputation of Manufacturer (Including quality)	45
Features of the radio	40
Convenience in operation	12
Other (includes American-made, prestige, size, performance)	3
Total	100

Table 4. Reasons for purchasing a particular brand of radio.

Purchasing Influences	Number of Amateurs (%)
Advertisements	42
Friend (Amateur)	31
QSO	15
Store display	10
Other (includes store salesman, family, used in contest)	2
Total	100

Table 5. Other purchasing influences.

quently mentioned in the survey*: Collins KWM2; Drake TR4C, TRF; Heathkit HW-101; Icom 701; Kenwood 120S, 520S, 820S; Swan Astro 150, 102BX; Ten-Tec Triton IV, Omni A,D; Yaesu FT-101, 101E.

It is interesting to note that only 25% of the amateurs surveyed had solid-state radios. The reason for this is probably because of the age of the sets. Table 1 indicates that although 33% of the amateurs have had their sets for 5 years or more, 23% have purchased new radios within the past year.

Types of Antennas	Number of Amateurs (%)	Reasons for Purchase
Triband yagi beam (3 elements or more)	48	Efficiency and gain. Work all bands. Best value for money.
Dipole	22	Low noise. Fits limited space.
Vertical	10	Low profile. Good construction.
Quad	10	Better DX.
Monoband yagi	7	
Minibeam	2	
Longwire	1	
Total	100	

Table 6. Antenna systems and reasons for purchase.

Why A Specific Radio Was Purchased

The buying environment is an important part of consumer behavior. Not only *where* a purchase was made, but *why* it was made are basic factors to consider.

As shown in Table 2, most of the amateurs bought their radios from either a local franchised dealer or by mail-order. The reasons for this are illustrated by Table 3. It can be observed that the reputation of the dealer, including service, and price are considered to be the prime reasons for buying a set from a particular place.

As discussed previously, the reasons *why* an amateur purchases a particular radio are important factors to consider in consumer behavior. Table 4 indicates that the reputation of the manufacturer, quality, and features of the radio are important elements considered by the amateur when purchasing an HF SSB radio.

Additional factors that influence an amateur's buying habits are illustrated in Table 5. It is interesting to note that 42% of those surveyed felt that advertising played an important part in influencing their final purchasing decision. Additional purchasing influences include friends (31%), QSOs (15%), and store display (10%).

Antennas

There are probably more on-the-air discussions concerning antenna systems than any other piece of amateur equipment. The purchase of an antenna, therefore, is an important factor to consider in relation to amateur buying habits. According to Table 6, the triband yagi beam appears to be the antenna most purchased by radio amateurs. 48% of the amateurs surveyed used this type of antenna. Table 6 also indicates the reasons *why* a specific antenna is being used.

Radio Accessories

An important part of amateur purchases includes radio accessories. The most popular accessories being used by the amateur are linear amplifiers, speech processors, audio filters, tuners, and keyers. Other accessories include monitor scopes, frequency counters, phone patches, and computers.

Occupations

Occupation is a basic index of social behavior. The results of the study show that people from all walks of life are presently enjoying the hobby of amateur radio. The occupations of radio amateurs as given in the survey include those shown in Table 7.

Conclusion

As previously discussed, this survey should be considered merely as exploratory in nature. The study was limited by the size of the sample obtained. This, however, is only a beginning in looking at the radio amateur as a consumer. ■

*It is not the purpose of this article to rate any one manufacturer's product over another. Also, not all sets mentioned in the study are listed; only those radios that were most frequently mentioned are given here.

Bob Cooper: Profile of a Pioneer

Editor's Note: In just three decades, television has won the hearts and minds of American society. *Newsweek Magazine* reports that the "average family member spends more than seven hours a day tethered to the tube." Innovations like community antennas, cable TV, and now reception directly from the satellites have nurtured our passion for video. Perhaps you prefer an evening of rag-chewing on 75 meters or chasing DX on the low end of 20 to watching the one-eyed monster—even so, you can't deny the impact that television has had on everyone's lives.

Tim Daniel N8RK
73 Magazine Staff

Six meters is open. My little portable SSB rig is hooked to a jury-rigged VHF TV antenna and I'm copying stations as far away as Florida. As I tune across the band, I find a pileup that rivals anything you hear on 20 meters. Eventually the furor dies down and I hear a weak but copyable signal:

"This is VP5D; the name is Bob and my location is Providenciales, one of the Turks and Caicos Islands."

The voice goes on to say that this is not a DXpedition, but rather a permanent station, so if you don't work it today, there will always be another chance.

VP5D is Bob Cooper, also known as W5KHT. When Bob is not handing out reports on six or ten meters, he is likely to be pursuing another form of electronic magic. Bob, you see, dreams about making high-quality, universally-available television a reality.

Cooper is the father of home satellite television. In just five short years, Bob ushered home reception of satellite TV from being a five-figure investment to the point where you can assemble a complete system for about $2000. Along the way, he wrote dozens of articles, including one for *73*, he had a column in *QST*, and he received coverage in publications like *Mother Earth News* and *TV Guide*. Coop's fame extends beyond the written word; he has appeared on Japanese TV news and more familiar programs like "PM Magazine."

To trace Bob Cooper's attachment to video, we have to go back to the infancy of commercial television. The Cooper family lived just far enough away from the nearest station to make reception a difficult task. As a youth, Coop combined his ham-radio-based knowledge of electronics with an enthusiasm for the growing world of TV. After all, building beams and preamps for VHF TV was not too different than home-brewing gear for six meters.

Bob's college training in broadcast journalism eventually led him to the cable TV industry where he was involved with the publication of trade magazines. When the satellite TV era began, Bob was already the veteran of the original TV explosion and the development of cable TV.

Coop's first exposure to satellite TV came at a cable TV trade show in 1975. Soon after, he began to work putting together a system of his own. By scrounging in the true ham radio fashion, he was able to build one of the first home satellite TV receiving systems for far less than the $25,000 asking price.

Along the way, Bob met other pioneers like Stanford University professor Tay Howard W6HD and Bob Coleman K4AWB who were working towards the same goal. Since new equipment was so expensive, these trailblazers relied on surplus units or, failing that, they home-brewed. There were no plans to follow, no kits to buy—only imagination and patience.

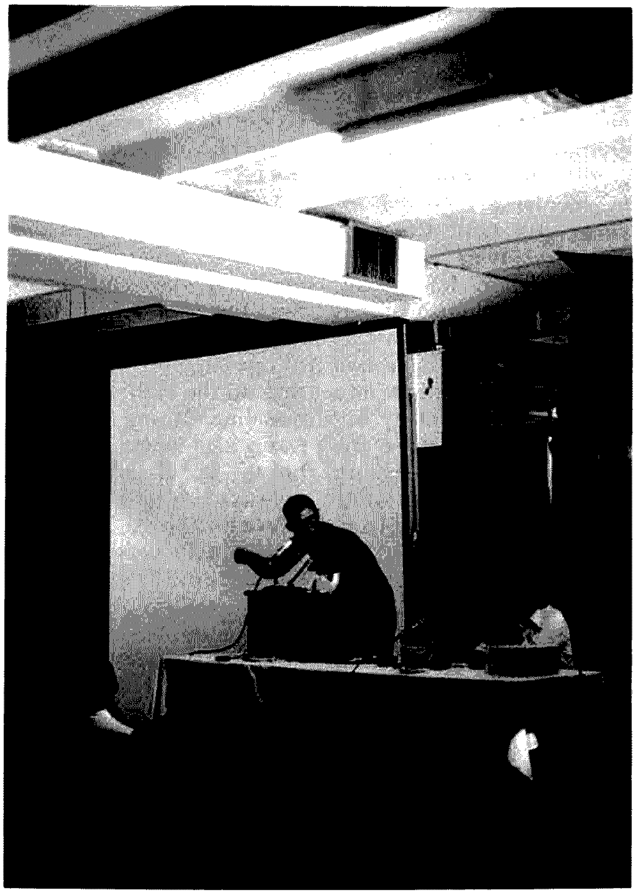
What Bob and a handful of other experimenters were accomplishing was of only passing interest to the professionals in the satellite TV field. The industry was content to keep satellite TV veiled in mystery and expense. Cooper, realizing the potential for the mass appeal of home satellite television receive only (TVRO), decided to go public. He did it in a big way. The *TV Guide* article in October, 1978, and subsequent coverage on the CBS Evening News alerted millions of people about the new technology.

Overnight, Coop was besieged with thousands of inquiries. He had created a demand which he is still striving to meet three years later. In those early days, there was no gear aimed at the home market. Before long, garage industries, often started by hams, sprang up. It was (and still is) a seller's market and anyone with a background in electronics had a tremendous advantage.

A digest for satellite TV enthusiasts, publishing manuals, and sponsoring seminars turned into a full-time endeavor and Bob made the plunge, committing all his talents to the

Bob VP5D.

Bob utilizes his extensive knowledge of the broadcast and cable TV industries to make high-quality TV a reality, despite the remote location. To Bob's left is a vertical interval switching unit which allows him to change signal sources rapidly, without any glitching. The monitor displays a computer-generated time, weather, and community information report. This is just one of the several ways that West Indies Video offers a local flavor to its programming.



The thrice-annual Satellite Private Terminal Seminars (SPTS) are sponsored by Bob Cooper. They offer an outstanding way for both hobbyists and dealers to find out the latest information about this dynamic industry. Approximately 1000 persons gathered at the August, 1981, seminar in Omaha. They had the opportunity to listen to such experts as Steve Gibson, who has combined the technology of computers and satellite TV for some very exciting results.

young industry.

The early days were not all milk and honey. The first Satellite Private Terminal Seminar (SPTS) in Oklahoma City was almost cancelled. A last-minute court hearing decided that the freedom to share information superceded a cable TV supplier's desire to keep the subject a mystery. (The legal questions that surround the satellite TV explosion are just beginning to see a thorough airing.)

Cooper was in on the growth of the industry from the start. *Coop's Satellite Digest* has become the favorite source for update information about the technology and the satellites themselves. How-to manuals, priced from $30.00, sell briskly. The thrice annual SPTS events are attracting over a thousand participants who gladly pay the $150 admission price. Coop had started the wave rolling back in 1978 and he managed to climb on top for a very successful ride. He let others manufacture the equipment, sell the dishes, and install them. His bag is information, something that a young industry can't live without.

New Beginnings

In 1980, the stage shifted from Oklahoma to a small, unknown island in the Caribbean. Just as the home satellite TV industry began to gain momentum, Coop pulled up stakes and moved his family to Providenciales, part of the tiny nation of Turks and Caicos. Besides donning a new callsign, VP5D, Cooper was on the brink of yet another video revolution.

The Coopers fell in love with the serene, isolated beauty of the Turks and Caicos on a vacation visit. It became harder and harder to return home on subsequent visits, so Bob and his wife Susan began thinking about making the island their new home. The prospering monthly magazine, manuals, and seminars gave the Cooper family the independence to choose a life in a home alongside a deserted beach, far from the hustle-and-bustle blacktopped world that most of us know. Bob was more than willing to escape the day-to-day hassles of being an industry leader so that he could concentrate on writing and video work.

The turning point came when Coop presented the plans for his new home to the island officials. Their curiosity about the satellite dish (doesn't everyone have a dish in the backyard?) led to a proposal that Bob share his signals with the rest of Providenciales. Cooper, who was familiar with the long, involved TV broadcasting license procedures in the US, was easily convinced. There were no existing rules for television broadcasting in Turks and Caicos. Being the first to attempt such a project meant that Bob would be able to write the book as he went.

The first priority, after moving to "Provo," was getting West Indies Video off the ground. A 16-foot dish was erected to catch program material relayed through SATCOM F1. The satellite downlink receiver provides a baseband video signal that modulates an "STL" (studio-to-transmitter link), in this case, a low-power transmitter on channel 7. The STL signal is aimed at a pair of yagis located on Provo's highest point, Blue Hill. From this "mountaintop" location, the signal is translated to be broadcast on channel 4 with 8.5 Watts of output power.

From the project's beginning there was a dual challenge. Establishing a reliable, high-quality TV ser-

vice is a major task by itself. Compounding those headaches are the drawbacks that accompany life on a remote island. Just about everything you and I take for granted has to be shipped in, involving a lot of expense and time. Commercial air service is spotty, barge traffic infrequent, and mail delivery takes three weeks, if you're lucky.

Many families have had the misfortune to move into a half-finished home, but how many have faced the challenge of setting up house in a TV station while the workmen are still hammering and sawing? The construction of a real home took a back seat to finishing the station. The control room doubled as an office, while the sound stage served as a bedroom for the two Cooper children.

The system on Provo evolved in stages. At first, the remote transmitter was powered by automobile batteries that required weekly recharging. Later, a solar-cell array took over, reducing the visits to once a month.

Until programmable switching equipment is installed, someone must be present in the control room every time a change in the program source is made. When Bob is gone, this task falls on his twelve-year-old son, Kevin VP5DX.

Except for the fact that only one channel is available, Turks and Caicos viewers are watching television like the premium cable channels available in the US.

Unlike most American television, West Indies Video has no advertising. During early stages of operation, the company is giving away the service. Because of the large expense of setting up the station and the poor advertising potential, Coop is planning to scramble the signal and charge a monthly fee for a decoder.

With 750 subscribers spread over seven islands, West Indies Video has chosen to use an addressable scrambler. After payment is received, the decoder will be activated for another month by a burst of digital transmissions. No money, no TV.

The islands' version of the Nielsen ratings is the phone calls that Bob and his family receive from dissatisfied viewers. Anyone wanting to invoke the wrath of an entire nation can do so by stopping broadcast of wrestling and boxing on Friday and Saturday nights. The most frequently heard complaint is that programs are not available 24 hours a day. It seems as though TV has taken the people of Turks and Caicos from being bored and isolated to being entertained and informed.

The low-power television (LPTV) concept which Cooper has proven in Turks and Caicos shows great promise for revolutionizing TV in the United States. The FCC is now allowing communities to enjoy specialized (educational, regional, religious, commercial) programming broadcast by 10- to 100-Watt UHF and

This is the site of the Cooper family's dream come true. Soon after this photo was taken, work began on a second building that will separate their home from the studio.

August 14, 1981

Dear Satellite Enthusiast,

We all have different dreams and aspirations. For the Cooper family, it had long been our hope that we would one day be able to move, permanently, to some quiet, out-of-the-way Caribbean island where our children could be raised to be self-sufficent, productive young people and where we could, as a family unit, make real and useful contributions to the development of "our island."

Very few people have ever heard of the Turks and Caicos Islands. A country with around 7,000 total population is not often in the headlines. Many maps do not show us to be here; the popular Caribbean tourist guidebooks seldom notice that we exist. Those that do mention us often make the incorrect assumption that the Turks and Caicos are an extension of and a part of the southeastern Bahamas.

Getting here is very difficult. Mail service is extremely poor; telephone service is only slightly better. But within 30 days of our arrival here, the Turks and Caicos had live (satellite-delivered) television. There was no national sport prior to our arrival; now, due totally to satellite television, professional wrestling is the national spectator sport. Nobody here had ever seen or heard world leaders before; they had never seen a baseball game, a play, or a movie. They had no idea what Sesame Street was, or where it was. They had never heard of James Bond or Barbara Walters. They were as far removed from the 20th century as a people could be.

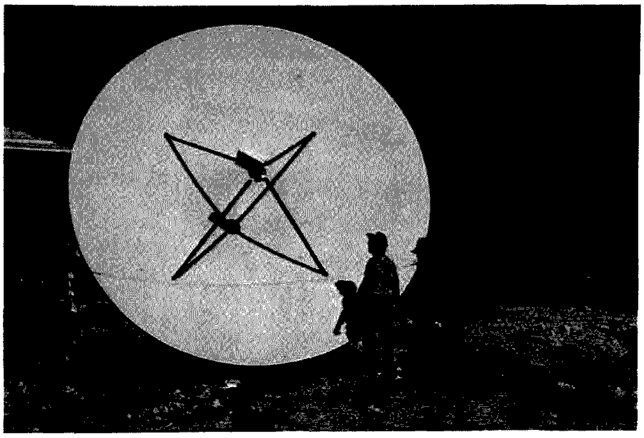
We take the responsibility of providing high-quality television to our country very seriously. We spend as much or more time making careful program selections as we do working out the intricate technical parameters of building a high-quality electronic service.

Satellite television can, in varying forms and shades, do much the same thing for areas closer to you than the Turks and Caicos, as it has done for our country. The satellite service has changed the complexion of the world in just a few short years. In the next five years, we will see such dramatic improvements and expansion of service that our efforts today will seem very primitive by reflection.

This is *the growth field* of the 80s and beyond. This is where the most exciting opportunities of your lifetime are to be found. The opportunities in this young field are totally unlimited. You can do anything you want to do, if you carefully learn the basics, carefully plan each step, and carefully select where and how you will do it.

Welcome to the 21st century. And if you are ever down our way, stop in and say hello to us on the shores of Grace Bay! We are the third satellite antenna on the left.

Bob Cooper



It takes a big dish to pull in studio-quality signals in the Turks and Caicos Islands. Bob, on the left, is with W2NSD/1 and WA1KPS.

VHF stations. Satellites will be the popular, low-cost way to distribute the video and audio to the local LPTV stations. Owning and operating these stations will not require the investment that accompanies one of the full service stations.

Ham radio operators have a long history of pioneering and popularizing new methods of communication. Concepts like single sideband, and now satellite television, have been transformed from expensive and complex mediums into something that is easily understood and affordable.

For individuals like Bob Cooper, radio is accompanied by "magic," whether the challenge is receiving a 4.0-GHz satellite signal or a pileup on six meters. ■

Subscriptions via first class mail are available directly from WESTSAT Communications, PO Box 434, Pleasanton CA 94566. Part I of 73's Satellite Channel Guide appeared in the November, 1981, issue.

Satellite Television Glossary
—part I

Editor's Note: Reprinted with permission of Reed Publications. This glossary is part of the 86-page *Satellite Television Handbook* available for $7.95 (add $2.00 for 1st class) from Global TV, PO Box 219-H, Maitland FL 32751. Part II of the glossary will appear in the next issue of 73 *Magazine*.

Active Device. An electronics component made using transistors to amplify or control a signal. See *Passive Device (next issue).*
Adjacent Channel Interference. Signal distortion because other signals in nearby frequencies are not properly filtered. A bandpass filter allows only the selected frequency band to pass through it removing adjacent channels.
AFC (Automatic Frequency Control). A satellite TV receiver feedback circuit which prevents the tuning oscillators from drifting away from the center frequency of the selected channel due to temperature change or other instabilities. A phase-locked loop demodulator usually provides an AFC output back to the LO.
AGC (Automatic Gain Control). A satellite TV receiver feedback circuit which controls the gain (amplification) of the i-f amplifiers so that the signal input to the demodulator will be constant, despite incoming signals of varying strength from different satellite transponders. AGC can be overridden by a manual gain control to make signal strength measurements in most receivers.
Alignment. The process of tuning (or tweaking) a circuit to compensate for the approximate tolerances of the components during assembly, using test equipment.
AM (Amplitude Modulation). An easy method of transmitting program signals on a carrier frequency where the relative strength (amplitude) of the carrier is made proportionally equal to the amplitude of the program signal. AM is simpler but more susceptible to noise than FM. Satellite TV uses FM for both audio and video modulation, but the user's TV set takes the satellite TV receiver's output and detects the video as AM, the audio as FM.
ANIK 1. A Canadian TV satellite operated by TELSAT. It has 12 transponders in the vertical format only and is located at 104 degrees west longitude on the geostationary orbit belt.
ANIK B. A Canadian TV satellite in the ANIK series located at 109 degrees west longitude. It has 12 vertical transponders.
Aperture Efficiency. The ratio of captured signal to the theoretical maximum for a given dish antenna/feed combination. The design goal is 100% aperture efficiency, but most TVRO dishes perform at only 50-80% to attain low noise characteristics and ease of construction. Some VHF/UHF antennas, on the other hand, can approach the 100% goal with an array of reflective elements.
ARO (Audio Receive Only). Small dish antennas used by radio networks for music and news programming distribution from TV satellites (mostly WESTARS). Dishes 2 meters and smaller have been considered by radio broadcast stations.
Artwork. A printed circuit design term which describes the printed circuit pattern of etched and conductor surfaces on a PC board.
Attenuator. A passive device which causes a known insertion loss in the signal transmission line. It is commonly used to prevent a very strong signal from overloading a receiver. They are also used as test equipment and in VHF/UHF broadcast reception to eliminate weak ghost signals.
Audio Subcarriers. The sound in a TV satellite composite signal is encoded in a narrow portion of the

video carrier, usually a high-fidelity FM signal at 6.2 or 6.8 MHz as measured after the main signal has been demodulated. Other satellite subcarriers can carry digital and text information as well.

Azimuth. Compass direction from due north measured in degrees clockwise, True north can be found by sighting the star Polaris at night, or by applying a local correction for magnetic deviation to a compass reading.

Azimuth-Elevation Mount. An inexpensive movable dish antenna mount and aiming system. It works like an oarlock where one pivot allows rotation in the horizontal plane about the azimuth angle from due north. The other pivot is the elevation above the horizon. This mount can be more difficult to aim than a polar mount. See *Polar Mount (next issue).*

Balun. An impedance-matching passive device located between a 75-Ohm coaxial cable and a 300-Ohm device, such as a TV set or VHF/UHF antenna.

Bandpass Filter. A type of electronic frequency filter which severely limits signal frequencies above and below the selected frequencies, preventing adjacent channel interference. Satellite TV receivers use these also to remove noise from around the edges of the selected channel, usually 30 MHz wide.

Baseband. This is the output signal of a video camera, videotape recorder, or satellite TV receiver before remodulation (so that it can be viewed on an ordinary TV set). A signal in a satellite TV receiver goes from 4 GHz through the downconverter to become i-f and then through an FM demodulator to become baseband. American NTSC TV bandwidth is 4.2 MHz at baseband.

Beamwidth. The beamwidth of a dish antenna is the angle of sky which can be illuminated (picked up or sent out) by the dish. Within that arc satellites can be seen from the TVRO dish. Large dishes have narrow beamwidths which reduce noise from its sides. Small dishes have wider beamwidths and are noisier, but easier to aim.

Bias. That part of an amplifier circuit which provides power for a transistor and supplies the energy for its output signal. On an LNA, the bias circuits are on a separate PC board.

Bipolar. A type of silicon transistor used in LNAs and other high-frequency, low-noise devices. They are superior in noise quality to ordinary transistors but are inferior to FETs, especially GaAsFETs.

Black Box. An engineering abstraction in which a device is considered only for its effect, not for its construction. Naive users can treat satellite TV components as black boxes until they are ready to learn more about them. They need to know only what they require and how to hook it together.

Blanking Pulses. That part of a video TV signal which for an instant blanks out the screen, enabling the electron beam to fly back to the start of a horizontal line or vertical frame. This is wasted time as far as information transmission is concerned and some methods for multiplexing data channels into a TV picture use the vertical blanking interval.

BNC Connector. Easy to lock coaxial cable fittings which interface signals in the i-f portions of a satellite TV receiver. They work well in the 70-MHz range.

Breadboard Circuit. A prototype of an electronic circuit in which changes are easily made, facilitating construction and debugging of the design.

Broadcast Satellite. A form of international frequency allocation where only the uplink stations are identified (licensed). See *Fixed Satellite for comparison.*

C Band. A loose military designation for 3.7-4.2-GHz microwave frequency band used for the downlinks of satellite TV signals. Wavelengths are between 8.10 and 7.14 centimeters (3.19 and 2.81 inches).

C/N (Carrier to Noise) Ratio. The ratio of the carrier strength and noise strength measured in dB. The higher the C/N, the higher the S/N and quality of the resulting TV picture. Above 11 dB is superior, above 7 dB is good, and below that the picture quickly becomes extremely noisy. See *also S/N (next issue) and FM Improvement (below).*

Cable TV. See *CATV below.*

Carrier. A strong signal occupying a communications channel which is modulated (AM, FM, etc.) to transmit program information. In an abstract sense, the carrier transports the program material from the transmitter to the receiver.

Cassegrain Antenna. A folded beam antenna which enjoys the advantages of a long focal length (high aperture efficiency and gain) without the disadvantages of lengthy and awkward feed supports. The subreflector is hyperbolic in cross section and is precisely adjusted to concentrate the incoming microwave fronts to a feedhorn located at the center of the dish. If the subreflector is elliptical in cross section, the antenna is also called Gregorian.

CATV (Community Antenna Television). Commonly known as cable TV, it has a central antenna tower (VHF/UHF/FM) together with a satellite TV dish antenna and captures high-quality broadcasts for subsequent sale through a signal distribution system, typically using coaxial cables to each home.

CCIR (International Radio Consultative Committee). A division of the ITU (International Telecommunications Union) which formulates international standards for radio communications, including the pre-emphasis and de-emphasis of satellite TV signals in a receiver.

CITT (International Telegraph and Telephone Consultative Committee). A division of the ITU (International Telecommunications Union) which formulates international standards for telegraph and telephone communications including uplinks and downlinks of satellite TV. See *also CCIR.*

Channel. A frequency band allocation which defines the limits of the contained broadcast carrier signal. In the USA, channels are allocated by the FCC.

Chip. An integrated circuit or section of a silicon wafer.

Chip Capacitor. A leadless capacitor small enough to be soldered directly on microstrip or stripline microwave PC boards. They must be used instead of ordinary capacitors because the leads would alter the inductive characteristics of the circuit. They are used to build LNAs.

Chroma. That part of the video signal which contains the color information.

Circular Polarization. Right- or lefthand screw sense of microwave signal polarization used by INTELSAT. A hybrid mode feed should be used to avoid the 3-dB

loss with standard linear (vertical and horizontal polarization) feeds.

Circulator. See *Isolator.*

Close-Captioned TV. A text service for the hard-of-hearing TV audience which decodes a text subcarrier and displays it at the bottom of the TV frame on the accompanying video picture. It does not interfere with the standard audio FM subcarrier.

CNR (Carrier to Noise Ratio). See *C/N.*

Coaxial Cable. A signal transmission line that is made using a center conductor separated from a shielding cylindrical outer conductor by a dielectric, usually polyethylene, sometimes air, in a low-loss application.

Commercial TVRO. A strong dish capable of withstanding hurricane force winds, an LNA with a lengthy MTBF (Mean Time Between Failures) and good noise figure, a drift-free, low-distortion receiver, and a high-quality modulator, all operating at a 3-dB margin above the receiver's FM threshold. This system supplies programming for sale through MATV or CATV distribution.

Common Carrier. An operator or lessor of satellite TV transponders which in turn leases them to other parties or transmits programming for others without controlling or owning the content. 4-GHz satellite TV is not legally a broadcast service and the FCC does not make the satellite TV common carriers (RCA Americom, Western Union . . .) abide by the constraints of broadcasting law.

Comparator. In an FM demodulator using a phase-locked loop (PLL), this is the electronic component which compares the phase relationship of the input signal with the signal from the tracking local oscillator (LO). The output signal from the comparator is proportional to the phase error between the two input signals and is used to control the LO.

Composite TV Signal. This is a combination of video picture, color, audio, and synchronization information.

COMSTAR I. An American satellite which can carry video but is operated by the telephone company, AT&T. Since it is underutilized, eventually it will carry more video. It has 24 transponders, 12 which are vertical linear polarized and 12 which are horizontal linear polarized. It is located at 128 degrees west longitude.

COMSTAR II. An American satellite, second in the COMSTAR series, which has leased 11 transponders to RCA for cable video programming. It also has 24 transponders and is located at 95 degrees west longitude.

COMSTAR III. An American satellite, third in the COMSTAR series, which like its sisters can be expected to carry more video programming in the future. It also has 24 transponders and is located at 87 degrees west longitude.

dB (decibel). A ratio expressed logarithmically which allows easy calculation of losses and gains. Two signals, S1 and S2, can be compared using dB according to the following equation: $dB = 10 \log (S1/S2)$. Often S2 is a known reference level. If a signal is 3 dB over the reference, then it is twice as strong; if it is -3 dB under the reference, then it is half as strong.

dBi. Decibel gain of an antenna over a reference antenna.

dBm. Decibel power of a signal over a 1-milliwatt reference.

dBW. Decibel power of a signal over a 1-Watt reference.

De-emphasis. A selective restoration of the high-frequency end of a satellite TV channel within the satellite TV receiver. This is performed after the FM carrier is demodulated to baseband. *See also Pre-emphasis (next issue).*

Detector. A demodulator circuit in a receiver which extracts the program signal from the carrier.

Dielectric. An electrical insulator which can carry an electric field when near a conductor. It is used to make transmission lines, microwave PC boards, and capacitors.

Diplexer. A section of waveguide which joins two microwave signals in an uplink Earth station.

Dipole. An active antenna element located in the feed which collects the concentrated satellite TV signal and conducts it to the LNA. It is called a probe in this case.

Directional Coupler. In an MATV or CATV signal distribution system, this passive device drops a signal line for a subscriber's TV set from the main trunk line. It is a superior performance signal splitter from the high level (strength) trunk line.

Discrete Components. Unlike an integrated circuit (IC), in this assembly technique each part is built separately and then assembled.

Discriminator. An FM demodulator circuit in a satellite TV receiver.

Dithering. See *Energy Dispersal Waveform.*

DOMSAT (Domestic Satellite). Distinguishes US and Canadian satellites from INTELSATs.

Double Conversion. This downconversion technique converts from 4 GHz to the final i-f (typically 70 MHz) in two stages instead of just one, so that potential image noise from the first mixer stage is eliminated. *See also Single Conversion (next issue).*

Downconversion. The process of converting the 3.7-4.2-GHz microwave signal down into a frequency range in which signal processing components are less expensive. Typically, this is a VHF frequency of 70 MHz.

Downconverter. A microwave part (consisting of local oscillators (LO), mixers, and bandpass filters) which accomplishes downconversion. This is the front end of a satellite TV receiver.

Downlink. The communication path from a TV satellite to its ground (Earth) stations.

Duroid. The brand name of a microwave printed circuit board specified in many LNA and downconverter plans. Mostly D-5880 226-127 from Rogers Corp. has been used.

Dynamic Range. The weakest through strongest signals that a receiver will accept as input. Signals which are too weak cause excess noise and signals which are too strong cause overloading and possibly modulation distortion.

East Coast Feed. Satellite TV programming scheduled for the convenience of US east coast viewers (Eastern Time Zone).

EIRP (Effective Isotropic Radiated Power). A measure of the relative strength of the satellite TV signal ex-

pressed in dBW. The USA ranges from 30 in Florida to 37 dBW at boresight in the midwest. Home satellite TV reception becomes much less expensive at 34 dBW and above. Footprint maps showing relative signal strengths in EIRP are filed at the FCC and ITU before the TV satellite is launched.

Elevation. Angle above the horizon measured in degrees. Zero is the horizon and ninety degrees is directly overhead. Elevation angles are used to aim the dish antenna at a TV satellite.

Energy Dispersal Waveform. This is a triangular-shaped signal at 30 Hz synchronized with the vertical blanking interval in the TV signal from the satellite which ensures that the signal will average its power out over the whole channel, even when just the carrier is present. This waveform is removed by the receiver after FM demodulation.

Etched PC Board. Acid is used over a mask (artwork) to dissolve away excess copper conductor leaving a conductor pattern on the PC board.

F/D. Focal-length-to-diameter ratio of a given dish antenna. Generally higher ratios yield better aperture efficiencies, but may be more susceptible to sidelobe noise.

FCC (Federal Communications Commission). The US agency which regulates communications, including satellite TV.

Feed. The antenna feed is a section of shaped waveguide which correctly collects the dish's reflected microwave signal and conducts it to the LNA's probe. Generally, a feed is uniquely designed for each dish antenna type.

Feed. A programming term which means a stream of programming material, for example, in the process of transmission over the TV satellite. Examples of its usage are: sports feed, east coast feed, and network feed.

Feedline. Coaxial cable running from the LNA to the satellite TV receiver.

FET (Field Effect Transistor). A low-noise, high-frequency transistor amplifier which has a current source, gate, and drain. The gate is a voltage-controlled resistor which regulates the power flowing from the source to the drain.

Field-Strength Meter. A CATV and TV test device used to measure power levels on a transmission line or VHF/UHF antenna.

Fixed Satellite. A form of international frequency band allocation where all the sending (uplink) and receiving (downlink) stations are identified. This is the current status of the 4-GHz TV satellite system. *See also Broadcast Satellite above.*

FM Improvement. The potential noise reduction in an FM signal due to the demodulation process in a satellite TV receiver. This figure is at most 38.6 dB and is attained above the FM threshold. Below this point it rapidly drops from 37.6 dB. Above threshold: S/N = C/N + 38.6 dB.

FM Threshold. An input signal level which is just enough to enable the demodulator circuits to extract a good picture from the carrier. With test equipment, static threshold is the point at which S/N drops more than 1 dB from the straight graph line: SN = C/N + 38 dB. Typically, FM threshold is 7-8 dB in a satellite TV receiver with threshold extension.

Footprint. A signal strength map showing the EIRP contours of equal signal from a TV satellite transponder on a given part of the Earth's surface.

Frequency Agile. This is a feature of satellite TV receivers which enables them to tune in all the 12 or 24 channels from a satellite. Receivers sold without this feature are dedicated to one channel and can be tuned by switchable crystals.

Frequency Coordination. A service which uses computers and a USA database to resolve potential or existing conflicts between various users of the same 4-GHz microwave band. The long-lines (long-distance) division of the Bell networks uses 4-GHz microwave towers throughout the USA. A TVRO looking in the direction of a transmitter may be jammed unless shielding can be used.

Frequency Modulation (FM). A method of transmitting program material which is more interference-free than AM. The frequency of the carrier signal is made proportional to the amplitude of the program signal.

Frequency Reuse. *See Polarization (next issue).*

Front-to-Back Ratio. The ratio in dB of the antenna gain in the forwards direction to the antenna gain in the rear direction. It is a measure of the noise potential from the rear.

G/T (Gain over Noise Temperature). A TVRO measure of quality expressed in dB. The higher this figure, the better the system. It can be improved by increasing gain or by decreasing the system noise. G/T (degrees Kelvin) = antenna gain/log (antenna noise temperature + LNA noise temperature).

GaAsFET (Gallium Arsenide Field Effect Transistor). This low-noise device, although expensive, is used in the highest quality LNAs. The term is pronounced gasfet.

Geostationary. Dubbed the Clarke Orbit in honor of Arthur C. Clarke who first described it. This circular orbit above the equator is precisely the altitude at which any size satellite will revolve around the Earth once every 24 hours. From the ground below, it thus appears parked in space overhead, and from above, one-third of the Earth's surface can be seen. TV satellites are separated by 4 degree intervals on this orbit to avoid mutual interference 38,000 km (22,300 miles) high.

Ghost. One or more dim copies in a TV picture caused by reflected VHF or UHF broadcasts. Also called multipath distortion, this is not present in satellite TV signals because extremely directional dish antennas are used.

GHz (Gigahertz). The standard abbreviation for billions of cycles per second. 3.7-4.2 GHz is the microwave frequency band allocated for satellite TV in the USA.

Global Beam. An INTELSAT antenna downlink pattern covering a third of the Earth's surface. They are boresighted at the middle of an ocean to provide service to nations all the way around the ocean basin.

Guard Channel. Unused portions of the frequency spectrum which are located between program channels to prevent adjacent channel interference.

Harmonics. Spurious signals produced by an oscillator circuit which occur at integral multiples above the resonant frequency of the oscillator. They appear

like overtones on a single piano note. They can cause design problems in a receiver circuit unless proper filters are used to remove unwanted harmonics.

HBO (Home Box Office). The most popular pay-TV network which is distributed on SATCOM F1.

Headend. The point on a signal distribution system where UHF/VHF/FM and satellite TV signals are captured, combined, and fed into the system.

Hemispherical Beam. An INTELSAT antenna downlink pattern consisting of two overlapping spot beams to cover a hemisphere.

High Pass Filter. A circuit which features high impedance for relatively low frequencies and low impedance for high frequencies, in effect blocking the low-frequency component in a signal. *See also Low Pass Filter and Bandpass Filter.*

Horn Antenna. A type of satellite TV antenna which is shielded against sidelobe interference. The incoming signal is reflected 90 degrees into a cone-shaped feedhorn. They are much more expensive than a dish antenna of the same aperture.

IC (Integrated Circuit). A solid state complex device which is mass produced on single silicon chips.

I-f (Intermediate Frequency). For satellite TV receivers, this is usually 70 MHz and is the frequency at which most of the signal processing takes place because the design is simplified and 70-MHz parts are less expensive than 4-GHz equivalents.

I-f Strip. A PC module which amplifies and filters the output signal of the downconverter in a receiver and inputs it to the FM demodulater. Its gain is controlled by the AGC circuit.

Image Noise. When a signal is downconverted using a mixer and LO, noise can be passed through the system that is on the mirror image frequency from the selected channel with the LO frequency as the point of symmetry. Subsequent bandpass filters remove this noise in double-conversion downconverters. A preselector filter in single-conversion receivers does the same thing.

Impedance. The relative ease with which signals pass through a device or conductor measured in Ohms.

Impedance Matching. The design of a signal interface such that the signal transmitted through it is maximized and the reflected signal is minimized. Standard impedance for LNAs is 50 Ohms and for satellite i-f circuits 75 Ohms. Most signal distribution systems interface at 75 Ohms impedance.

INTELSAT. International (primarily non-communist) satellite agency whose member nations lease transponder capacity on its satellite system. It provides at least some TV in all parts of the world, but signal EIRP is often quite less than US domestic satellites.

Isolator. A device which is a one-way valve for microwave signals which prevents stray receiver signals from leaking out past the LNA onto the antenna. It also facilitates the design of the LNA by impedance matching the feed probe to the first LNA amplifier stage. Most LNAs have an isolator attached between the CPR-229 feed flange and the main amplifier box.

Kelvin. The scientific temperature scale which measures thermal noise characteristics of microwave devices. Performance improves with decreasing noise temperature. 0° K equals −273 degrees Celsius and −459 degrees F. The Kelvin scale starts at absolute zero and is graduated like the Celsius scale.

Launch Vehicle. A NASA term for the rocket used to place satellites in orbit. For TV satellites this is usually the Delta, although the Space Shuttle will take over this job in the 1980s.

Level (High or Low). In communications, level means the same as amplitude or relative strength.

LO (Local Oscillator). A closely-connected frequency source which is typically controlled by a resonating crystal or by an input voltage. *See also VCO and VTO (next issue).* They are a major component of downconverters and demodulators in receivers.

Lobe. An area of strong reception in a graph of antenna gain versus angle off boresight. In highly directional dish antennas, the front lobe is high gain and the side and back lobes are much weaker.

Look Angle. Pointing angles for aiming an antenna at a TV satellite for a given site. This term is also used when referring to antenna elevation alone. It is important when considering possible site obstructions or extra antenna noise due to a low elevation (look angle).

Low Pass Filter. A circuit which features high impedance for relatively high frequencies and low impedance for low frequencies, in effect blocking the high-frequency component in a signal. *See also High Pass Filter and Bandpass Filter above.*

Luminance. That part of a video signal which controls the brightness of the image on the TV screen.

TVRO Receivers: The Inside Story

—Satellite Central, part II

Getting 4-GHz signals down to watchable video is no easy feat. Noted satellite TV pioneer Paul Shuch N6TX once observed that there are perhaps as many receiver designs as there are receiver designers. Despite the fact that satellite TV is new, we've already experienced at least two generations worth of improvements in receiver design philosophy. Both methods employ your garden-variety superheterodyne conversion principle. But that's about the only similarity.

The major hassle is dealing with the microwave signal itself. The components are either too expensive and hard to get or they are incredibly fragile and roll over and turn belly up when you approach them with a soldering iron! So the logical solution is to convert the troublesome 4-GHz signal down to something we can massage with parts we can understand, like coils and capacitors rather than pea-sized chip caps and PC board traces that are alleged to be tuned circuits! There will be plenty of time for that later. For the time being, let's just get our feet wet.

Referring to Fig. 1, we have a typical dual-conversion receiver design. This is the "classic" or "by-the-book" method used by most commercial firms today. A voltage-tunable local oscillator (LO) mixes with the incoming 4-GHz signal down to a 400- to 1200-MHz first intermediate frequency (i-f). This is in keeping with the spirit of a textbook approach of selecting an i-f about one-tenth of the incoming signal (the "divide-by-10" rule). After some needed amplification, the signal is mixed again down to what is known as baseband (because we're done with conversion), amplified even more, and then detected with either a PLL or discriminator circuit. Baseband is generally 70 MHz, an industry standard.

So Much For Basics

The key points worth noting here are conversion to a lower frequency where we can crank in lots of easy-to-find gain . . . and sticking to the rules. But why do that? Well, conversion makes a lot of sense. After all, the incoming signal may very well be around −50 to −60 dBm at 4 GHz and a 564 PLL detector chip wants something quite different before it will deliver pictures.

But who made the rules about dividing by 10 and that nonsense? The guys that got there first, of course. They did some arithmetic and made a discovery of some importance. A single-conversion design has problems if you chose a first (and only) LO just 70 MHz from the desired signal. You get down to baseband a lot quicker, but you get something else in the bargain . . . the image signal as seen in Fig. 2.

Remember from last month's Satellite Central that the satellite band (3.7 to 4.2 GHz) is 500 MHz wide. So even an LO spaced some distance away, whether above or below the

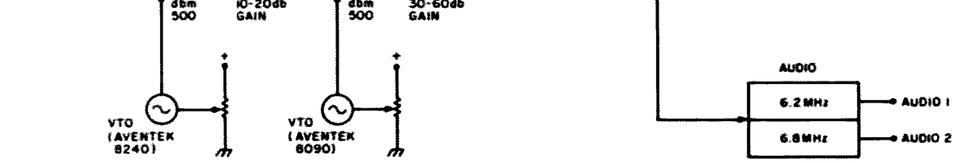

Fig. 1. Dual-conversion design. The first VTO mixes with the downlink signal into the first i-f amplifier. The second VTO is fixed. Gain distribution may vary in different designs. The 70-MHz bandpass filter must be flat in the passband for best results.

desired frequency, can still convert an undesired image signal to baseband.

Now you could filter out the image on the front end, but you would have to make the filter track with the LO to remove all images as you tuned. At these frequencies, a tracking filter is no easy beast to tame. So rather than wrestle with the problem, receiver designers such as Stanford professor Taylor Howard W6HD adopted the dual-conversion philosophy and proceeded to knock 'em dead with the first low-cost TVRO! The design has become a sort of standard of this new industry with several manufacturers duplicating it piece by piece, even to the last resistor, probably because Howard made his complete design available to anyone.

An Interesting Turn of Events

As an historical note, Howard designed his receiver with available components. The key word here is "available." While you could indeed call Avantek and order an 8240 voltage-tuned oscillator (VTO) or call Vari-L for a DBM-500 mixer, you also could sit around and tear pages off your calendar while waiting for delivery! I had time to traipse all over California scouting up surplus dishes as the clock ticked away.

Clearly, something had to be done. Several amateurs, most notably Robert Coleman K4AWB, made an interesting discovery. Not only were surplus mixers lying around, but single conversion could be made to work! A quick doodle with pencil and paper suggested it might be worth the trouble.

If we want to receive transponder 17 on SATCOM 1, its frequency is 4040 MHz. Setting the LO down 70 MHz, to 3970 MHz, will indeed pull transponder 17 into our 70-MHz i-f, but also the image frequency as well, which is 70 MHz below the LO. Now it happens that's dead-on transponder 10 at 3900 MHz. So it can't possibly work! Or can it? We know that RCA and COMSTAR birds have 24 transponders. And we also know that the odd-numbered transponders (such as transponder 17) are vertically polarized. But if the even transponders are horizontally polarized (such as transponder 10), then our receiving antenna will be cross-polarized to the interfering signal and hopefully ignore it!

So it appears that single conversion does indeed work despite the prospects of image noise. There is a limit. As a rule, cross-polarization may only reduce the image signal 20 dB, but recent efforts at image-reject mixer design and a new tracking filter eliminate this annoyance, as seen in Fig. 3.

Baseband At Last

Nearly all of the foregoing problems are a result of wideband FM video detection circuitry not working too well at high intermediate frequencies. However, it can be made to work. A few manufacturers have designed excellent discrete PLL circuits that work at 700 MHz, making signal conversion a piece of cake. But 70 MHz remains as the i-f most used at the moment.

As I mentioned before, quite a few receiver designs utilize a 564 PLL detector chip at the end of the 70-MHz i-f chain. The problem here is that the 564 is rated to only 50 MHz. Still, a handful of 564s will always yield several that work at higher frequencies, depending on the source. But a drastic improvement is 564 operation can be had by cleverly dividing the 70-MHz i-f signals by two with a cheap JK flip-flop chip like a 74LS112 and operating it at 35 MHz!

Other detector designs in use today are quadrature detectors and linear discriminators. They offer advantages and disadvantages when compared to the PLL. While the PLL offers excellent performance at receiver threshold and below, it takes second place to the discriminator and quadrature-type detector when signals are well above threshold. Remember from last month that we must try for a carrier-to-noise ratio of about 10 dB or better for clear pictures. (That translates to at least a 12-foot dish and a 120° LNA for most locations in the USA.) Still, you don't need nearly as much gain for a PLL as you do a discriminator.

To work properly, the discriminator must see a signal that is amplified well into limiting. This is the main reason why quality receivers look bad compared to cheapy models when tested on marginal systems.

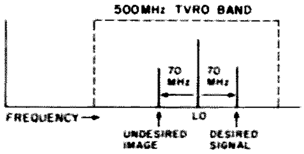

Fig. 2. An in-band LO can produce an undesired image signal. Luckily, this image is cross-polarized to the desired signal. It's not enough for perfect pictures, so other methods are necessary to ensure adequate image rejection.

SATELLITE TV HAM NET!

Tune in Sundays at 1800 GMT on 14.311 MHz for the Satellite TV Net. Lindsey Riddle W5JG in New Orleans is Net Control. Then Ken Rae WB0POP takes the reins at 1900 GMT. You'll be amazed at what you can learn in just an hour or so.

But just cranking up the gain is not enough, as some experimenters will tell you, because not all i-f amplifiers will limit symmetrically. A weak location or a smaller dish can still be made to work, thanks to the PLL.

But suppose you've dug deep into your pocketbook and found enough money to allow you to build your system so it operates well above threshold? Then the discriminator or quadrature detectors really shine because the PLL can sometimes break up an other-

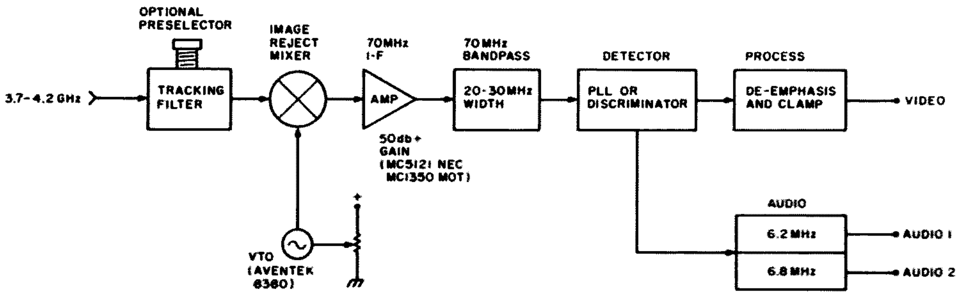

Fig. 3. Single-conversion design. The problem with single conversion is that an image signal can be detected. Tracking filters and clever image-reject mixer design can reduce the image by 20 dB or more. A good high-gain LNA will overcome mixer losses in this design.

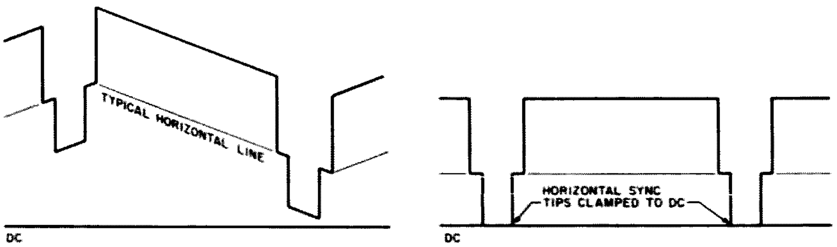

Fig. 4. (a) Video demodulator output showing video riding on energy dispersal wave. (b) Energy dispersal wave eliminated by dc clamp circuit.

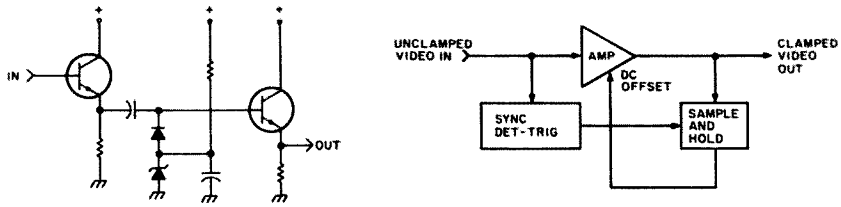

Fig. 5. Typical diode clamp circuit used in economy receivers vs. feedback clamping taken from voltage samples of the video signal during the sync pulse interval.

wise fine picture when tracking wide deviations. You see an annoying streaking effect in the video. Tweaking the bandwidth can help to cure this problem.

Now if the PLL works pretty well at the 35-MHz reduced i-f, you might wonder what would happen if we divided again and again down to nearly dc. Perhaps the only problem with that idea is that we bump into Carson's rule along the way. Simply stated, the practical bandwidth of a frequency modulated signal should be equal to twice the sum of the maximum frequency deviation and the highest modulating frequency. If we know the typical frequency deviation as 10.75 MHz, then twice the highest modulating frequency (how about 5 MHz for video?) when added to this deviation yields a projected bandwidth of 31.5 MHz. Actually, it could be more if we lay in a 6.2-MHz or a 6.8-MHz sound subcarrier. Bandwidth = 2 (10.75 MHz + 5 MHz) = 31.5 MHz.

Watching Intelligent Noise

Okay, how wide an i-f is necessary? It really depends on your carrier-to-noise ratio (C/N). If you have a small dish in a weak footprint, you may very well be at threshold or below. A wide i-f bandwidth will only make matters worse because you will appear to be seeing more noise than video. While our eyes tend to integrate enough to discern intelligence, nice and clear pictures are what we really want. If you worked out the downlink equations we discussed last month, you well know that restricting the bandwidth by more than Carson's rule can make a big improvement in C/N. But there is a limit.

The problem then is to figure out how to squeeze a wide car into a narrow garage! If we don't mind scratching the chrome, we can just barely get it in. Likewise, we can reduce the i-f bandwidth to 17 MHz or so and have viewable video, but at the expense of the finish on the pictures. More importantly, the carrier-to-noise ratio may improve enough to make the pictures very watchable. That is until you wonder what happened to the definition and why the frizzy effect when flat color fields are transmitted. Clearly, there is a limit to bandwidth restriction. Whatever was out there at those wide deviations is gone now!

You can reduce the distortion somewhat if you turn down the color and watch everything in black and white, but that's taking a giant step backwards. In fact, you might just as well turn down the sound, too, because all you'll hear is the sound of birdshot being dropped on a cookie sheet! Nothing takes the place of a large dish and a good LNA . . . nothing.

Beyond Detection

The sound channel is easy to detect. It is merely an FM subcarrier that may be 6.2 MHz or 6.8 MHz. Most receivers are equipped to receive both inasmuch as detection for each subcarrier can be done in a single consumer TV sound section IC such as the CA3065. As a rule, 6.8-MHz subcarriers are used on RCA/SATCOM birds, while 6.2-MHz subcarriers are found on Western Union/WESTAR birds. Nothing is standard, so a switchable or tunable sound subcarrier detector is necessary.

Other subcarriers may be located above video on some transponders. Background music and slow-scan services as well as data transmissions can be found. We will be sure to look at methods of recovering these signals in future installments of Satellite Central.

Satellite TV signals are pre-emphasized according to a CCIR curve. This amounts to a 10- to 12-dB boost on the high end of the video. An LC network smoothes the curve back out as well as wiping out the sound subcarriers before further video amplification.

Fig. 4(a) shows the output of a typical detector after de-emphasis. Notice the unclamped video appears to be riding on a triangular wave at the frame rate. This is known as the energy dispersal waveform and is mixed in at the uplink transmitter. It is simply a way to keep the main carrier moving during the unlikely loss of video. That way, every microwave link in the country on that frequency doesn't get sprayed with an interfering carrier from space. As a practical matter, it's quite the other way around. In any event, a clamp nails the energy dispersal waveform down to dc in Fig. 4(b) and we have clean video. If this waveform is not removed, the picture will flicker at the 30-Hz rate.

Some TVRO receivers have modulators in them so the detected video and sound can be fed directly to a TV set. Others may only have a one-volt audio and video output. While a cheap TV game modulator can be used to get the picture into channel 3 or 4 of your TV, the results leave much to be desired. Sometimes it's simply the result of poor design. But poor shielding is the likely culprit. The modulator output

manages to find a way back into your 70-MHz i-f chain (remember that channels 3 and 4 would fall into the i-f bandpass of 55-85 MHz). The solution is to skip the re-modulation process and feed the audio and video into a quality TV monitor or a regular TV modified for audio and video input. On the other hand, an effortless method is to simply feed the TVRO receiver into a video tape recorder and use its internal modulator!

Obvious Differences

While price may be the major obstacle to designing an ideal receiver, experience with the problems you're likely to encounter runs a close second. As we learn more about what can and can't be done, we can make adjustments to our thinking and our design. For example, the VTO used in most receivers is a real hassle. You have 500 MHz worth of tuning spread over about a 270-degree twist on the pot. That's a lot for manual tuning (over 470 standard broadcast bands!), so afc is needed, if not for sheer operator ease, then for the very small amount of drift you'll likely encounter. Fancy receivers use a synthesizer and eliminate the problem. That takes more parts, which adds to the price . . . but not too much if you do it yourself!

You can sometimes discern a quality receiver design from an economy version by observing how well the energy dispersal clamp circuit functions. While simple receivers use a simple diode clamp, more expensive (and better designed) versions employ voltage feedback methods such as seen in Fig. 5.

By far the most interesting difference in receivers today is the concept of splitting them up into pieces as some economy-minded manufacturers have done. This eliminates the need for expensive coax to carry the 4-GHz signal from the LNA to the receiver. They simply mount the mixer, VTO, and first i-f at the dish and run the lower i-f to the house on RG-59. Some really clever LNA manufacturers are building the whole works into a single LNA and downconverter, calling it an LNC!

Tricks Worth Trying

If you want to try your hand at receiver design, go ahead with the certain knowledge that much of the foregoing works well enough to be a good point of departure for your own design fantasies. Microwave genius Steve Birkill G8AKQ, of Sheffield, England, downconverts into a broadbanded UHF TV tuner. He does the first conversion to UHF at the antenna so that RG-59 can be used rather than the expensive 4-GHz stuff. The UHF tuner then performs the second conversion down to an i-f the PLL can handle.

The cost of tuners like Steve's is around 25 bucks. Some of the newer varactor tuners are very broadband except for a coil in the last stage. A few moments of work are all that's necessary to modify the stage for the wide bandwidth needed for good pictures. Does the idea sound interesting? Then how about following the tuner with a very cheap TV IC amplifier chip such as the MC1350 for your i-f amplifier? And if you don't like that PLL, then why not use an MC1357 FM quadrature detector chip instead? Rex Rhoads, an engineer with RCA, has done it with excellent results. By the way, the construction cost of his entire receiver using this very conventional circuitry (no secret chips or tricks) is way under $100!

The time is right for you to join in the fun of receiving TV from space. If you have a question regarding the topics we cover here, feel free to drop me a line (letters only, no calls please). Sorry, I can only answer mail that is accompanied by an SASE.

You can find out more about receivers by reading two back issues of *73:* November, 1979 ("The Satellite TV Primer," Bob Cooper) and December, 1979 ("Low-Cost Receiver for Satellite TV," Paul Shuch). ■

The Nelson Parabolic TVRO Antenna Manual
by Nelson Ethier
reviewed by:
S.F. Mitchell WA4OSR and Richard Christian WA4CVP

As the foreword in the *Manual* states, author Ethier has no formal microwave training, but "he is an excellent student of obscure textbooks and an avid do-it-himselfer. . ."

The Nelson Parabolic TVRO Antenna Manual starts with a general discussion of parabolic dish design and describes the relative advantages of a parabolic antenna over the spherical antenna. These advantages include the fact that the focus never changes and that the entire surface works to collect the signal. A brief review of noise, noise measurement (dB and degrees K), calculation of antenna gain, wavelength, and formulas to find parameters follows. Nelson then gives the arguments for different focal ratios and the reasons why he selected an f/d (focal point to diameter) ratio of 0.375.

Very detailed treatment is given to the calculation of the parabolic curve for his antenna. The formula and a method of laying out the curve on graph paper is presented along with a table with the curve calculated in one-half-inch steps for a 10-foot dish with a .45 f/d ratio or a 12-foot dish with a .375 f/d ratio. These calculations are very simple and can be done on a calculator with a square root function.

The most informative part for us was the section on choosing the antenna to suit the needs of a particular site. A brief discussion of the significance of the carrier-to-noise ratio (CNR) and an example of its calculation gives you an idea of the type of picture quality you should be able to obtain at your location.

The material between page 11 and the *Manual*'s end on page 31 is devoted to the actual construction of a 12-foot parabolic antenna, feed, feedhorn, and polar mount. The antenna is built on a form which must be fabricated with plywood and fiberglass rods. The form is constructed and covered with 0.020 sheet aluminum which must be cut and formed. Fiberglass is then applied to the back of the aluminum. Reinforcing ribs of wood and urethane are then added and a second layer of fiberglass is applied. The finished antenna appears to be quite sturdy. Although no estimate of the antenna's cost is given by Ethier, we estimate that it would cost between $750 and $1000 and require as much as two months of steady work to complete.

Pages 23 to 29 describe the fabrication of the feed, feedhorn, and mount. The feed itself is an aluminum tripod bolted to the rim of the dish. It appears that this system, which involves using an antenna rotator to turn the horn, may put undue stress on the feed assembly.

Overall, we feel that the *Manual* gives a lot of good information, but it gives very little that we haven't seen elsewhere. The best part of the manual is the first ten pages where antennas and system requirements in general are discussed. The actual construction of the antenna may not be practical since a commercial antenna can be as cheap, if not cheaper. *The Nelson Parabolic TVRO Antenna Manual* is well worth $15.00, but at the $30.00 cover price we feel that it is very expensive. *The Nelson Manual* is available from the publisher, Satellite Television Technology, PO Box G, Arcadia OK 73007.

The Ace Portable Synthesized VHF Receiver

—for those times when listening is enough

Karl T. Thurber, Jr. W8FX
317 Poplar Drive
Millbrook AL 36054

The sight of a 2-meter handie-talkie (HT) strapped to the belt has long become a telltale sign that the wearer is an amateur radio operator—whether it be at a hamfest, on the street, in a public place, or wherever. There's no question that the personal two-way portable has revolutionized amateur radio with a "go-anywhere" mobility and convenience that was unheard of just 8 or 10 years ago.

Nevertheless, there are times when even the smallest of amateur HTs are a bit much to tote around. In many situations, sporting an obvious HT marks one as a nut, freak, or fuzz and can even set one up for a ripoff. Frequently, it's not absolutely necessary to be able to transmit; a small monitor receiver may do the trick. What is, in fact, needed in many situations is an ultra-small, programmable, synthesized monitor that is truly of pocket-sized dimensions.

A few years back, the Henry Radio Co. took a giant step forward in this area by marketing a line of low-cost pocket receivers, available in several models: a VHF-high band scanning radio, a 12-channel nonscanner, a two-channel VHF-high monitor/paging receiver, and a single-channel UHF receiver. These four radios, available with accessory continuous tone-controlled squelch system (CTCSS) and two-tone decoders, filled a variety of needs as monitor or pager receivers for hams, volunteer firemen, auxiliary police, civil defense personnel, and the like. The sets, with sensitivity typically in the range of 0.8 microvolts for 20-dB quieting and including an internal nicad pack, were not only shirt-pocket size, they were small enough to fit in the palm of the hand. Their main drawback, common to all such fixed-tuned, crystal-controlled receivers, was the fact that they were just that, *fixed tuned*, meaning that additional (expensive) crystals were required for expanded frequency coverage. For example, in the case of a 12-channel VHF receiver, $60 worth of crystals at $5 a shot would be required for full utilization. The same technical developments in frequency synthesis that caused the crystal-controlled HT to go out of favor have had almost the same effect on monitor receivers such as these, as

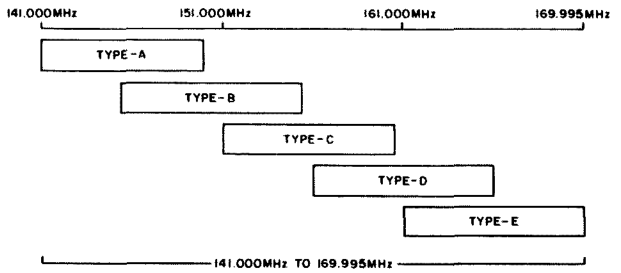

Fig. 1.

well as mass-market police and fire monitor table radios and scanners of the type made by Bearcat, Regency, and Radio Shack.

A recently introduced VHF FM PLL synthesized monitor, the AR-22, manufactured by AOR, Ltd., of Tokyo and sold in the US by Ace Communications, Inc., of Tustin CA, has effectively harnessed the new technology and made practical a wide-range VHF communications receiver in a coat- or shirt-pocket package. The new radio, which is 5¼" H × 2½" W × 1" D, weighs but 7.1 oz. (200 grams) with the battery pack installed. The AR-22 is designed specifically for applications where people on the move must reliably monitor transmitted VHF signals, even under adverse conditions. The AOR unit is capable of covering the VHF frequency spectrum from 131.000 MHz to 179.995 MHz and is offered in five discrete ranges emphasizing monitoring requirements of different radio services including amateur, police, government, marine, railroads, etc. As can be seen from a look at Fig. 1, the two receiver configurations of most interest to amateurs are Type A, covering 141.000 to 149.995 MHz, and Type B, covering 146.000 to 154.995 MHz. The maximum frequency coverage of each set is listed as 8.995 MHz with little or no degradation of performance at the band edges.

Designed for FM reception, the radios feature PLL frequency systhesized, dual-conversion superhet circuitry with low-noise CMOS logic to cover the 8.995 MHz range specified, in 5-kHz increments.

The direct frequency readout enables positive

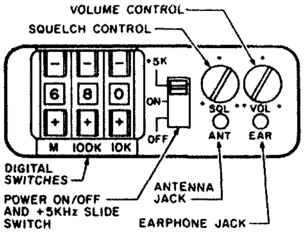

Fig. 2.

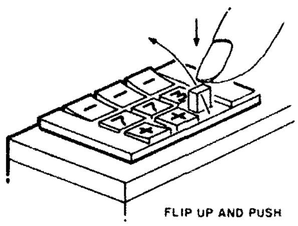

Fig. 3.

frequency control without the battery drain introduced by LEDs or LCDs.

The two most significant digits are factory-programmed. For example, in the Type A (2-meter) receiver, the base is 140.000 MHz; this does not require reprogramming. As indicated in Fig. 2, the third, fourth, and fifth digits are individually controlled and set by the three-section digital thumbswitch on the radio's top panel. The slide switch allows for 5-kHz reception increments—this feature allows the receiver to monitor the exact transmitted frequency or to be set for standby at a predetermined frequency. The receiver is set to the desired frequency using the (+) or (−) flip-up push-button located adjacent to the digit to be changed—the button is simply flipped up (+ or −), then pushed down to set the desired frequency (see Fig. 3).

The receiver's specs are impressive and are, in fact, comparable to good amateur HTs. Claimed sensitivity is 0.2 microvolts EIA for 12 dB SINAD, with an audio squelch sensitivity of 0.2 microvolts. The radios incorporate what the manufacturer calls "electric stage tuning" for nearly 9-MHz-wide coverage. As such, the input and rf stages of the set are tuned electronically by variable tuning diodes which are inserted into each stage to obtain maximum sensitivity as well as maximum selectivity and out-of-band spurious and image signal rejection. Adjacent channel rejection is spec'd at ±12.5 kHz at 60 dB down, while spurious and image attenuation is about 50 dB. Frequency stability is excellent, within ±10 ppm (parts per million) over the operating temperature range of −10 degrees C to +60 degrees C.

The physical construction of the little unit is very sturdy. The set is designed and tested to operate under adverse, knockabout conditions. The high-impact ABS plastic case housing protects against physical shock, while the double-sided glass-epoxy printed circuit board ensures a tight ship inside.

Audio output is sufficient, considering the physical size and power limitations imposed. Rated audio output power is 100 mW into an 8-Ohm load at 10% THD (total harmonic distortion); power consumption is but 25 mA with receiver squelched, rising to 100 mA at the rated 100 mW audio output level. The internal battery furnished is a rechargeable 4.9-volt, 225-mAh nicad pack.

For a refreshing change, there are no accessories that must be purchased to achieve acceptable and convenient operation. Included are a wall-type charger for charging the 225-mAh nicad battery pack, the pack itself, standard 7" and mini (4") helical (rubber duck) antennas, a 20" wire lead antenna, and an earphone. The only optional accessories offered by the manufacturer are a leather carrying case and vehicular charger.

The set's full set of specs is given in Fig. 4. How did the little radio perform on the go?

We selected the "B" model, which covers 146.000 to 154.995 MHz, for purchase. This choice allowed us to cover both the populous top 2 MHz of 2 meters, plus a 7-MHz chunk of the adjacent public service and commercial bands, allowing bonus coverage of local police, fire, highway, paging, mobile radiotelephone, and taxicab frequencies. The radio's battery was found fully charged upon receipt (in use it takes about 10 hours to fully charge the radio with the set turned off). The fact that the battery was charged allowed us to check out the radio's performance within a few minutes of unpacking it. When used with the standard-size (7") rubber duck antenna, we found reception to be entirely adequate from medium- to high-level signal sources, actually about equivalent to that expected of the typical amateur HT when using a rubber duck antenna. Reception on the smaller (4") mini-duck was, predictably, not as good, but represented a good space-saving compromise when receiving strong local signals. The 20" wire lead antenna did not seem to offer any improvement in reception over the larger rubber duck.

Technical Data

Frequency Range	131.000 MHz to 179.995 MHz
Maximum Frequency Coverage	8.995 MHz with no degradation of performance
Receiving Mode	Frequency Modulation, 16F3
Receiver System	PLL frequency-synthesized dual-conversion superheterodyne
Usable Sensitivity	0.2 uV EIA 12 dB SINAD
Audio Squelch Sensitivity	0.2 uV at threshold squelch, adjustable
Selectivity	Adjacent channel rejection ± 12.5 kHz) greater than 60 dB
Spurious and Image Attenuation	Less than 50 dB
Frequency Stability	Within ± 10 ppm over the operating temperature range
I-f Frequencies	1st 10.7 MHz, 2nd 455 kHz
Audio Output Power	100 mW into 8-Ohm load at 10% THD
Power Consumption	25 mA at receiver squelched 100 mA at 100 mW audio output power
Operating Temperature Range	− 10° C to + 60° C
Battery	Rechargeable nicad battery pack, 4.9 volts and 225 mAh
Physical Size	5¼"(H) x 2½"(W) x 1.0"(D) without knobs
Weight	7.1 oz. (200 grams) with battery pack
Frequency Selection	3 digits of digital push switches and slide switch
PCB	Double-side glass-epoxy printed circuit board
Housing	High-impact ABS plastic case

***Specifications subject to change without notice.**

Fig. 4.

Frequencies were easily and rapidly punched in using the three digital push switches and slide switch (for 5-kHz split-frequency operation). The volume and squelch controls, located behind the earphone and antenna jacks, respectively, on the top of the radio, are very small and were very difficult to operate with the antenna and/or headphone plugs installed. Fortunately, for most purposes, these controls can be set and forgotten except for occasional minor adjustment. Audio quality was excellent and was of more than adequate volume for most applications; there was no trace of case vibration even at high audio levels.

Other than the minor inconvenience caused by the size and placement of the two top-panel controls (volume and squelch), no significant drawbacks were noted in operation. The synthesized feature was found to be very handy, for the same reasons that practically the only HTs sold today are synthesized models. All that seems to be missing is a scan feature, LED or LCD frequency display, and a belt clip—all, perhaps, in the next model. The one real disappointment we noted was in the instructions, which bordered on the unreadable. Fortunately, the radio's operation was straightforward and didn't require resorting to the instructions—usually a last resort, anyway, to most hams! No schematic diagram was supplied.

The little radio fills a real need for an inexpensive, frequency-agile portable monitor receiver; at $150, it represents a worthwhile investment. For more information, contact Ace Communications, 2832-D Walnut Ave., Tustin CA 92680. Reader Service number 478. ■

Beginner's Guide to Antennas

—not just for Novices

For a number of years I have been teaching a ham radio licensing class on a more or less regular basis, and as many instructors have found, the class itself is only a start.

As the students receive their licenses, they invariably return with a set of questions which point out the difficulty of translating the knowledge, newly won, into practical use. The following conversation has been repeated dozens of times and is aimed at the universal problem of selecting and erecting an antenna for a new ham station.

Question: I just received my license and got a good buy on an allband rig. I am out of money, don't have much time, and want to get on the air as quickly as possible. What antenna and what bands should I start with?

Answer: Put up a 40-meter dipole. This will give you a chance to make a large number of contacts, day or night, weekday or weekend. In addition, you can load it up on 15 and work DX if the sunspot cycle is in a favorable position. See Fig. 1.

Q. Can I use insulated wire?

A. Sure—as long as you remove the insulation at the point where you connect the feedline. Also, make sure that the wire you select does not stretch. If it does stretch, you will have to keep cutting the wire back to the proper length periodically. Your best bet is to buy copper-coated steel wire. The copper gives you good conductivity and the steel core keeps it from stretching.

Q. I have a roll of "thin" coax (RG-58 or RG-59). Can I use it instead of buying the more expensive RG-8?

A. In the HF ham bands (80 through 10 meters), as long as you have a fairly short feedline run, say, 100 feet or less, you won't notice any difference.

Q. Gotcha! We learned that the feedline impedance should be 70 Ohms for a dipole and some of these coax cables have a 50-Ohm impedance. Can I still use them?

A. Again, for short runs of feedline in the HF bands, there will be no noticeable difference. The swr might be a tad higher, but this won't make any difference. Just one caution on coax: You can buy some relatively inexpensive coax that was originally sold to undiscriminating and unsuspecting CBers. It normally costs half or 2/3 of the cost of brand-name coax, and as you can guess, there is a good reason for the lower price. Be suspicious. Cut away a short section of the outside insulation and see how much of the inside insulator is covered by braid. If there are large spaces and you can see a good part of the inside insulation, be careful. You may be invit-

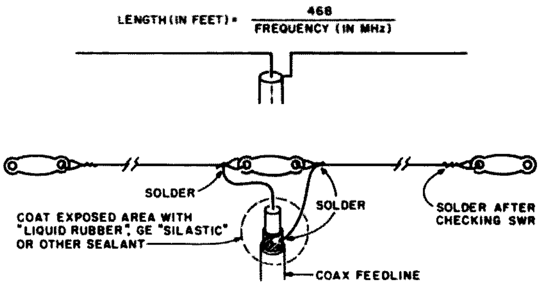

Fig. 1. For 40 meters at 7.125 MHz. L = 468/7.125 = 65.68', or 65' 8".

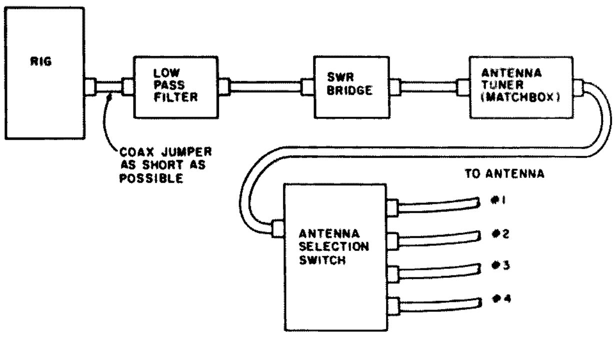

Fig. 2.

ing problems if you decide to use it.

Q. But what about the swr? Can I operate with a 2:1 or 2.5:1 swr?

A. Well, for many years the most popular ham antennas used an swr of 5:1 or 10:1. These antenna/feedline systems used open-wire line, and the key here is low losses in the feed. If your rig will operate with a high swr, there is no reason to fight to get the swr down to the nice round value of 1:1 as long as the loss in the feedline is low. Again, in the HF bands with short feedline runs, an swr of 3:1 won't affect your signal at all.

Q. Will my rig operate with a 3:1 swr?

A. Most rigs with tube finals will, as long as you don't keep the key down for long periods. Solid-state finals are a different problem. Most have swr protection, which means they sample the swr and reduce their power if the swr goes too high. Given a choice, I would try for an antenna with a low swr. But if it means spending 5 minutes tuning up every time I QSY (change frequency), I would accept the higher swr in the interest of convenience and extend the life of the finals by not keeping the key down so long tuning.

Q. What about antenna tuners? In fact, I have read about tuners (matchboxes), low-pass filters, swr bridges, and coax switches. They are all connected to the rig. In what order do you connect them and why?

A. See Fig. 2. Start at the coax jack of the rig and connect the low-pass filter with as short a coax jumper as possible. This means that harmonics will be attenuated before they have a chance to run around long pieces of coax and possibly radiate. Next in line is the swr bridge, since you are interested in matching the rig to whatever follows. The tuner is the next item, followed by the switch and the antennas themselves. Thus, you select an antenna with the switch, utilize the tuner to make the antenna and feed look like an acceptable load, and monitor the swr (and relative power out) with the bridge.

Incidentally, it might be a good idea to make up a tuning chart for each of the frequencies you use. Write down the frequency, settings of the controls on the rig, settings of antenna tuner controls, and antenna selected. When you want to QSY, simply set all controls as shown on the chart, and then tweak them to get maximum power out and minimum swr. Normally, if you operate all over a band, you don't have to log these settings any more than each 50 or 100 kHz on 80 and 40, every 100 or 200 kHz on 20 and 15, and 500 kHz on 10.

Q. I live in a small valley surrounded by hills. Are there any special precautions I should take in selecting an antenna?

A. On 80 and 40, a dipole, inverted vee, or longwire will work fine. However, on 20, 15, and 10, you might *not* want to pick a very high gain beam or quad. A really good beam or quad radiates at a low angle, almost horizontally, and will simply pump your precious rf into the hills. Antennas such as the popular triband beams have to sacrifice some of this low-angle characteristic in order to operate on three bands. As a result, more of the rf is sent up at a slightly higher angle (up to perhaps 40 degrees, or so) and this will probably top the hills around you. Alternately, seriously consider tilting the beam or quad so that it radiates up to clear the hills.

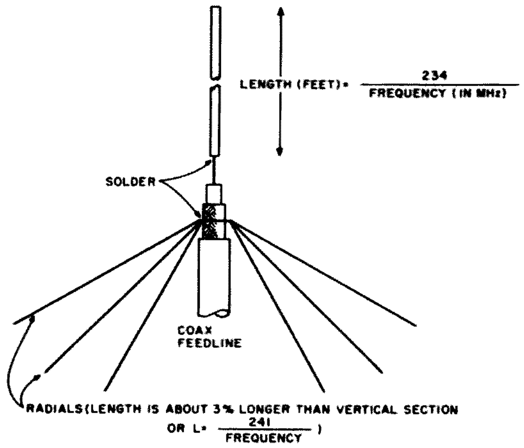

Fig. 3.

Q. I can't put up a big antenna. I don't have the space or my XYL/husband or neighbors would object to a big tower. How about one of these vertical antennas? See Fig. 3.

A. Verticals, especially full-size verticals, work fine. But they do require radials. Each radial is about a quarter wavelength long, and while you would like over 100 radials, you should have as many as you can put up for each band you will operate. I suggest 2 each as a minimum on 80 and 40, and 4 each as a minimum on 20, 15, and 10.

Q. But I thought verticals were good where you don't have much space?

A. They will work with only the coax feed acting as a single radial. However, they work much better when you add radials cut to the proper length, and they work best when you have a very large number of radials. Every experienced ham has a story of how he worked DX on a 10' wire hanging out the window. But for the most consistent and best results, verticals need radials, and lots of them.

Q. What about mobile whips? Can I mount one on the house and use it? Cars don't have radials.

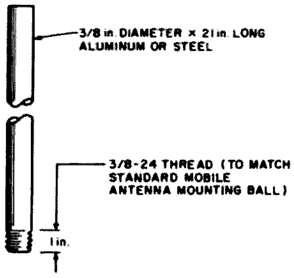

Fig. 4.

A. On a car, the metal body is used as the ground plane in place of radials. In addition, this sort of antenna system is from 2% to 15% efficient. The physical limitations of a car make us accept this loss, but you can do much better at home.

Q. Speaking of cars, I still have a standard mobile mounting ball on my car that I used to use for my CB antenna. Can I use it for a 2-meter FM rig?

A. You will have some loss and you will probably never get the swr down really low, but you have two choices. First, you can buy one of the commercial 2-meter antennas which mount in the standard mobile ball thread. These are 5/8 of a wavelength long but have a loading coil which makes them look like 3/4 of a wavelength. This is an odd number of quarter wavelengths, so the input imped-

ance is about 60 or 70 Ohms and you can use the old mount and coax feeder. You also can take an aluminum or steel rod, cut to about 20 inches, and thread the lower inch to match the thread in the ball (Fig. 4). You now have a quarter-wave vertical again using the old ball mount and coax feeder.

Q. As long as we are salvaging CB antennas, surely on 10 meters I can use the 27-MHz Loudengrabber V that I have mounted on my roof.

A. You probably can use it on 10 with an antenna tuner, but it might be less efficient than simply replacing it with a 10-meter vertical. If you want to try an experiment, connect it to your 2-meter FM rig. It might make a real nice (and quick) vertical for 2m. But don't try this unless your 2-meter rig has swr protection in case the swr turns out to be very high.

Q. One final question: I have a wire which I used to listen to the ham bands before I got my license. It runs out the window, over the roof, under the apple tree, and about 10′ above the ground around the garage. If I use an antenna tuner, can I make do with this wire?

A. We would all like 90′ towers and large array antennas. Most hams have to make do with what they have without structural steel work. Sure, you can use the wire, as long as it is high enough so no one can touch it while you are transmitting. Generally, you want any antenna to be as high and in the clear as possible. But if you can only run a short wire, use it. It will work and you will have many hours of good contacts. ■

The Daiwa Infrared Wireless Microphone

—is the mike cable obsolete?

Dave Ingram K4TWJ
Eastwood Village #1201 South
Route 11, Box 499
Birmingham AL 35210

If you're still fumbling with microphone cables that get entangled in auto steering wheels and gearshift levers or continuously drag papers off the home station desk, Daiwa Industries has a new item worthy of investigation—a cordless infrared microphone. Reflecting shades of both Star Trek and James Bond, the infrared mike adds a refreshing freedom to "confined" activities in both mobile and home setups (although the system is primarily designed for mobile operation). While this little gem might be considered by some to be of questionable utility, I found it one of the most logical and useful items available in many moons. The only problem I've encountered is deciding which rig should be connected to the infrared mike system. Imagine being able to move around your home desk or in your auto while using a small mike clipped to your shirt front or pocket, and you'll surely agree the mobility of a cordless mike opens many new possibilities for enjoyment of your radio equipment.

How It Works

The Daiwa infrared mike system is composed of 3 items: the microphone, the infrared beam sensor, and the control unit. Activating the microphone's push-to-talk switches on the mike's circuitry and the infrared-emitting LEDs which carry information to the small sensor unit. Output from the sensor goes to the processor unit, which connects to the rig's microphone input.

The infrared ray is not directly visible, indicating operation in the mid- to far-infrared range of approximately 2 to 15 microns (a micron is one-millionth of a meter). I suspect the sensor unit's front cover also acts as a tuned filter for the specific infrared range used, since cigarette light, match or flame flicker, flashing LED readouts, etc., are completely ignored by the sensor. Some elaborate ray-modulation tricks may also be employed, but a schematic diagram wasn't available for studying the system when my early unit was acquired.

Only three connections are required for the system, and it's ready for use. First, 12 volts dc is applied to the controller; second, the sensor is plugged into the controller; third, the controller's output is plugged into the station's transceiver. The system is shipped with a 4-pin connector wired for Kenwood rigs, but it can be quickly rewired or replaced as necessary. A drop-in charger for maintaining the mike's small internal battery is included in the controller unit's left side, while audio processing circuitry is located in the unit's right side.

The charger's operation is fully automatic with a single LED indicating functions. The LED illuminates when the mike's depleted battery is being charged. The LED begins flickering approximately one time per second when the battery approaches full charge, and it extinguishes completely when the battery reaches full charge. Since the charger then switches off, the mike can be left in its socket until the next time it's needed. This means that in a mobile installation, the mike can be left in the controller's case overnight for worry-free recharging and storage.

The infrared mike's effective working range is between 3 and 5 feet, as measured from LEDs to sensor. This distance is substantially more than necessary for mobile installations, since the sensor's suggested mounting place is above the windshield's indoor rear-view mirror. Audio quality of the infrared mike is extremely good; my unit actually sounds better than the factory mikes supplied with the rigs with which it's used (Kenwood, Yaesu, and Comtronix). Each time the infrared mike's push-to-talk switch is keyed, a piezoelectric beeper in the controller chirps softly to indicate proper operation of the system.

Using the Infrared Mike

Since this "liberated microphone" doesn't reflect the common sensation of being in direct-wired contact with its associated transceiver, we suggest initially using it with the home setup or a small audio amplifier before using it mobile. This will allow you to become familiar with mike sensitivity, maximum sensor-to-mike working range, etc. I used the transmitter

monitor in my FT-901DM for this purpose. If your rig doesn't feature a speech monitor, mike operation can be monitored through the use of a stereo amplifier or transistor radio (tune radio off stations, and connect controller's mike output wires between the volume control wiper and ground; one "side" of the volume control is usually connected to ground also).

My home setup operation with the infrared mike was so enjoyable that I postponed mobile use for a couple of weeks. The infrared sensor was stuck to my wall-mounted speaker which was positioned substantially lower and approximately twice the distance of Daiwa's suggested top-of-windshield moulding strip location. The system worked great, but the mike had to be held vertically and "talked across" because of the low-mounted sensor. On-the-air comparisons reported the mike sounds as good or better than my time-proven Shure 526 or Yaesu mike. Since an in-shack television reacts wildly when my 2-kW amplifier is going full bore, I expected problems with the cordless mike. Fortunately, however, I was pleasantly surprised. The mike performed magnificently . . . and I could enjoy the flexibility of moving anywhere around the operating desk without the ties of a mike cable.

Mobiling with the Infrared Mike

The true pleasures of a cordless mike operation were realized when I mated the unit with my 2-meter mobile rig. The infrared sensor was placed above the inside rear-view mirror while the controller was mounted with adhesive pads (supplied) to the transceiver's bottom. I could move anywhere within the (full-size 1981) car's interior and conduct smooth QSOs in a very enjoyable manner. Bright sunlight, unusual reflections, and temperature variations had no effect on the system. The microphone worked as flawlessly as a wired mike. A slight amount of wind noise was noticeable when a window was open or the air conditioner was operating at maximum. Loud noises outside the auto occasionally modulated the rig, emphasizing the need for Daiwa's optional F-4 windscreen. Since the system's audio processing circuitry doesn't skimp on output level, the windscreen is definitely beneficial for mobile operations.

Summary

The Daiwa infrared mike system is one of the most enjoyable accessories I've used with an SSB or FM transceiver. The unit's versatility and relatively low cost are particularly attractive, since it allows one to enjoy a touch of class without a drastic financial outlay ($79.95; 4 optional windscreens, $7.95). My only complaint on the whole system is the somewhat flimsy push-to-talk switch on the mike (it's also a push-on/push-off, unless you have a light touch). The switch hasn't given any problems, and I'm not considering modifying it—I'm merely finicky. I'm quite impressed with the sincerity and creditability of MCM Communications, the U.S. distributor for many Daiwa products. They seem committed to caring for their customers. For more information, contact *MCM Communications, 858E Congress Park Drive, Centerville OH 45459.* Reader Service number 477. ■

What's It All About, ASCII?

—RTTY technology update

Authors' note: Since this article was prepared in early 1980, our experience has been that most stations that have computers also have dual-mode originate/answer modems and do not require the modem translator at the repeater. They transmit with their modem in the Answer mode and switch to Originate for receiving. This makes all data on both the input and output appear at the 2025/2225-Hz tone pair which is suitable for simplex operation. Also, since the 300-baud speed of the 103 modems is no better than we can do over the phone, our current activity is the collection of Bell 202 compatible modems that operate at up to 1200 baud. These modems are becoming available on the surplus market and require no modification for operating half-duplex over the radio. They were chosen because they use the same familiar FSK as both the 103 and RTTY modulators but at a 1200/2200-Hz rate.

On March 17, 1980, the Federal Communications Commission (FCC) permitted the use of the American Standard Code for Information Interchange (ASCII) in the Amateur Radio Service.

Specifically, the FCC permitted US radio amateurs to transmit:

- ASCII as defined in the United States of America Standards Institute (ANSI) Standard X3.4-1968.
- Speeds up to 300 baud between 3.5 and 21.25 MHz using F1 emission.
- Speeds up to 1200 baud between 28 and 225 MHz using F1, F2, and A2 emission.
- Speeds up to 19,600 baud on frequencies above 420 MHz using F1, F2, and A2 emission.

The above permission was contained in the FCC's Third Report and Order under Docket No. 20777. It represents a significant step forward and marks the beginning of a new era of data communications on the ham bands. Possibly, it will play a part in a marriage of personal computing and amateur radio. It is not as permissive as some had hoped for in order to be able to experiment with speeds higher than those permitted and to transmit other codes, including some not yet devised. We look forward to additional action by the FCC along these lines to liberalize the rules on digital transmissions in order to permit true experimentation in the Amateur Radio Service.

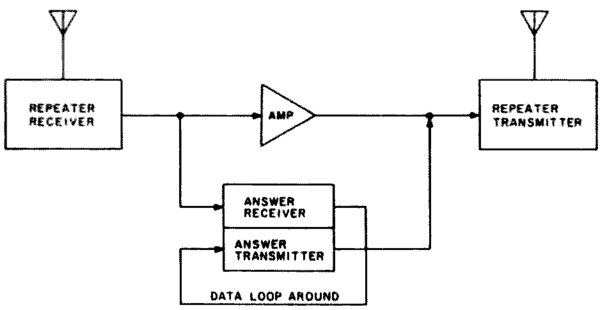

Fig. 1. Addition of an answer modem at the repeater with its received data echoed to its transmitter allows multiple users to send and receive data using only originate modems at their stations.

Outside the United States, the use of radio teleprinter codes other than Baudot (otherwise known as the Murray code or the International Telegraph Alphabet No. 2) varies from one country to another. Many have no regulatory mandate for the use of the Baudot code in the first place. Amateurs in other countries with import or monetary restrictions may have difficulty obtaining modern equipment employing ASCII. In Great Britain, amateurs can use any radioteletype (RTTY) code defined by documents of the International Radio Consultative Committee (CCIR), according to a Home Office interpretation obtained by the Radio Society of Great Britain.

In September, 1978, Canadian amateurs were given permission to transmit computer data in packet form on frequencies above 144 MHz under a new class of license called the Amateur Digital Radio Operator's Certificate. Canadians have subbands 221.0 to 223.0 and 433.0 to 434.0 MHz reserved exclusively for packet transmissions.[1, 2, 3, 4]

While ASCII was originated in the United States, it is well on its way toward becoming the world standard computer and RTTY code. It also is known as International Standard 646—ISO code (Reference 2)—and International Telegraph Alphabet No. 5. Like the Morse code, variations of ASCII exist for the alphabets of other languages including Cyrillic, Kata Kana, Arabic, Hebrew, Greek, and special letters used in Scandinavian languages.[5] As in the US, it is a sure bet that radio amateurs in other countries will be among the first to use personal computers. Many industrialized countries have home computer stores. So, it is only a matter of time before everything falls into place for the marriage of amateur radio and computers on a worldwide basis.

As soon as ASCII became "legal" in the US, a number of amateurs went on the air to try out the new mode. In the Washington DC area,

most radio amateurs involved with computers had equipped themselves with modems (modulator-demodulators) for communication on the phone lines. Baudot operation on 2 meters had been dead for about a year in anticipation of the FCC's ruling. Eighteen stations were ready to go during the first hour that ASCII was allowed; 14 stations made successful two-way ASCII contacts. We have heard scattered reports of 2-meter ASCII activity from other areas of the country. On the high-frequency (HF) bands, a number of stations were on the air using 110-baud ASCII on the RTTY frequencies. Many amateurs who wanted to get on ASCII as soon as possible did not want to reconfigure their stations *until* the details of the FCC ruling were known. We hope to see them on the air soon.

Technical Standards

Comments on Docket 20777 on file in the FCC public reading room indicated that the writers favored three basic approaches, divided almost equally. About a third said the *bandwidth* should be limited. Another third suggested that *speed* be regulated. The remaining third took the FCC to task for trying to regulate something best left to self-policing amateurs. The FCC decided to regulate *speed*. On other particulars, the respondents suggest that the FCC forget about specifying the parity bit because home computers tend to ignore it. They recommended making both synchronous and asynchronous transmission legal to permit experimentation. Finally, they recommended that the bit order be from the least to most significant bit according to common practice.

You will note that there are no restrictions imposed by the FCC on use of the parity bit, the number of stop bits, the use of synchronous or asynchronous transmission, the bit order, the maximum frequency shift for F1 emission, or the modulating tones for F2 or A2 emissions. These matters are open to experimentation and will evolve according to the needs and preferences of amateurs.

For starters, most amateurs will completely ignore the parity bit. In many cases, stations will transmit a parity bit, but the receiving stations will not process it. However, some agreement on the use of the parity bit is desirable because this feature can help reduce transmission errors. The number of stop bits will likely be 2 for 110 baud and 1 for 300 baud and up. Two stop bits are needed by a number of ASCII printers which operate at 110 baud.

Most amateurs will use asynchronous transmission to begin with because of the availability of asynchronous equipment. Synchronous ASCII transmission is an interesting area for amateur experimentation. The bit order is likely to remain least significant bit to most significant bit. Frequency shifts and modem tones for amateur ASCII transmissions are unlikely to settle down for quite some time. Amateurs presently are using modems of the type used for Baudot RTTY and those designed for telephone line communications between computers.

On the phone lines, the data communications convention for personal computers is to use a modem which uses Bell Telephone 103/113 standards. This permits serial, asynchronous, full-duplex communication at speeds up to 300 baud on the telephone line. It uses audio frequency shift keying (AFSK) FM with frequency assignments as shown in Table 1.

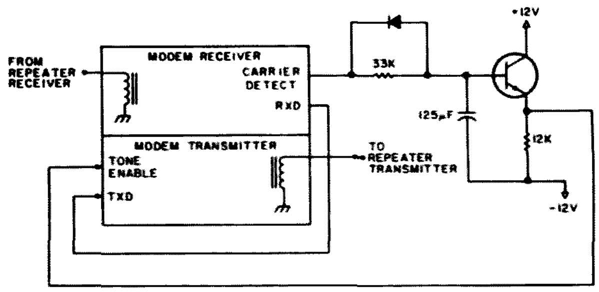

Fig. 2. An RC combination with an emitter-follower slows down the carrier-detect signal from the receiver so that at least 4 seconds of carrier are required before the modem transmitter is activated.

Bell 103/113-compatible modems are available for personal computers in several different forms. One is the originate-only modem, the cheapest type, which is all one needs to originate calls to other computers. Originate-only modems use the "Originating End" tones given in Table 1. Another is the answer-only modem for computers which never make outgoing calls. The third variety is the originate/answer modem which can handle calls either way.

Separate for the moment the modem function from that of coupling to the telephone lines. The least expensive route is to use an acoustical coupler which mechanically connects to the telephone handset. Home-brew acoustical couplers can be made from small transistor radio speakers and spray-can plastic caps. A direct connection to the telephone lines can be made by means of an FCC-approved telephone data coupler, which is considered a must for modems with answering capabilities.

These modems and data couplers are now readily available to home computerists and will, no doubt, have an impact on the standards to be employed by radio amateurs. The extent to which this will replace existing amateur radio FSK keyers and converters or tuning units (let's just call them modems) deserves some thought.

HF ASCII RTTY

It seems likely for two reasons that there will be a mixture of ASCII and Baudot on the HF bands for a while, using existing RTTY modems. One is that some of the non-US amateur RTTYers find it difficult to obtain ASCII gear initially. Another is that the average HF RTTYer has hundreds of dollars invested in a good modem designed to copy through the noise, interference, and fading encountered on HF. HF RTTY modems are far better in this respect than most Bell 103/113 modem designs. So, it would be a step backward to ditch a well-engineered HF RTTY modem in favor of one designed for use on the telephone line. Nevertheless, some 103/113-type modem operation on the HF bands is to be expected, and the 200-Hz shift employed might not be too difficult to live with.

RTTY modems such as

Function	Originating End	Answering End
Transmit	1070-Hz space	2025-Hz space
	1270-Hz mark	2225-Hz mark
Receive	2025-Hz space	1070-Hz space
	2225-Hz mark	1270-Hz mark

Table 1. Bell 103/113 modem frequencies.

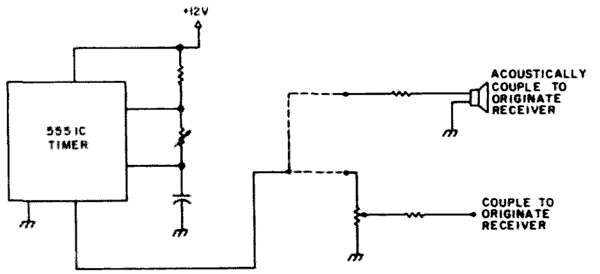

Fig. 3. A 555 oscillator at 2225 Hz can be used to fool an originate modem into thinking it is connected to an answer modem so that it will enable its transmit tones while operating half duplex. This is not required if a minor change inside your originate modem can be tolerated.

the ST-6 can be modified easily to handle both existing RTTY tones of 2125-Hz mark and 2295-Hz space and 103/113 tones by retuning audio filters. Clearly, a contest of wills and pocketbooks is in the offing before this incompatibility is resolved. Our feeling is that the old 170-Hz shift should be kept for those stations still running 60-wpm Baudot and that 200-Hz shift will be used for 110- and 300-baud ASCII.

ASCII RTTY via OSCAR Satellites

OSCAR satellites present a special problem for RTTYers for either ASCII or Baudot. The managers of the satellites do not like any type of FM (such as FSK) to be used because the signal has a 100% duty cycle. They prefer lower duty-cycle signals that are keyed on and off in order to keep overall loading on the satellite within reasonable levels. Thus, any RTTY modem for communications via OSCAR satellites should be capable of on/off keying. Because of noise characteristics, for equal results a good on/off-keying RTTY demodulator needs to be a bit more sophisticated than its FSK counterpart. For the 1980s, an on/off keying capability will be a must for RTTY modems.

VHF/UHF ASCII RTTY

In contrast to HF and OSCAR RTTY, we expect to see ASCII with Bell 103/113 tones dominate VHF/UHF RTTY. This seems fairly certain because of the decline in Baudot RTTY activity on the VHF/UHF bands in recent months.

As noted earlier, the cheapest way of communicating with a computer is to use an originate modem. Manufacturers' surplus originate modems are available for as little as $25. This works fine if the originating station connects with another station which has an answer modem. Another look at Table 1 will convince you that two originate modems cannot talk to each other. The same is true of two answer modems. Those with originate/answer modems can talk to anyone; indeed, this is the case with many computer owners.

Modem Translator Experiments

A scheme was needed to make two originate modems compatible. The solution: placing a modem translator at the WD4IWC/R 2-meter repeater which serves the Washington DC area RTTYers and amateur radio computer enthusiasts. Just as the repeater operates on two *radio* frequencies to translate incoming signals to the correct output frequency, the translator modem changes incoming *audio* tones from originate modems into answer modem tones on the repeater output. As a result, all originate modems listening to the repeater output are able to copy all signals.

The advantages of this scheme are:

- Uses exactly the same modems as used over telephone lines.
- Requires no special, unique hardware.
- Eliminates the need for the more expensive answer modems at all stations.
- Regenerates data at the repeater, realizing some improvement in signal-to-noise ratio.
- Does away with the problem of who is originating and who is answering, which normally is needed in duplex modems.

Implementation: Hardware installation was fairly simple. An answer modem initially was connected as shown in Fig. 1. The lines required to the repeater were an audio tap off the receiver and a tap into the transmitter audio line. The received data line coming out of the modem receiver was then echoed back into the modem transmitter so that an exact replication of all data present on the repeater input was reproduced on the repeater output.

The only other signal required is an *enable* signal to tell the modem when to initiate its transmit tones. This was done in the initial installation by simply taking the received data *carrier-detect* line, delaying it up to five seconds with an emitter-follower and a capacitor, and using that to drive the transmit enable line of the modem transmitter. With the resetting diode shown in the circuit of Fig. 2, any momentary loss of carrier would reinitialize the five-second turn-on delay, thereby preventing the transmit tones from coming up on anything but a valid signal. The controls as described above make the modem an autonomous device requiring nothing but power and the two audio connections.

Controls: Later, additional control circuitry was added to disable the function entirely. This is needed during periods of experimentation with other types of modulation on the repeater and to aid repeater troubleshooting. A final refinement was to use the data carrier detect to open up the repeater audio line between the receiver and transmitter. This ensures that noise on the signal received at the repeater is not added to the transmitter output.

Installation: To minimize repeater maintenance problems, the answer modem described here was packaged in modular form. A separate ac power supply was included in the module.

One Hitch: There is a minor problem with the scheme described here due to the manner in which commercial originate modems operate. Many originate modems wait for the receipt of the answer carrier before the originate-transmit tones are enabled. This is done by sampling the receive carrier-detect line in the originate modem and looping it back to the originate-transmit enable. This feature poses no problem for a station while receiving because it will hear the answer tones being transmitted by the repeater. But, on transmit, since the receiver is most likely disabled, the originate modem will not hear the answer tones. Fortunately, this is a wiring change only for those individuals who are using surplus or home-brewed gear. They can wire the modem-transmit tones to come on only when the radio transmitter is keyed on. For the casual user who has a nice expensive com-

mercial modem that should not be attacked with the soldering iron, there is another way to coax a modem into originating tones first. A simple switch inserted into the carrier-detect line to enable or disable this function is a solution. Another one is to use a 555 timer in an oscillator circuit to generate 2225-Hz tones to fool the modem into thinking it is on line. These tones may either be hard-wired or acoustically coupled into the modem during transmit to enable the originate transmitter. A possible circuit is shown in Fig. 3 and can be constructed for less than $2.

Conclusions

FCC approval of ASCII will be a boon to amateur radioteletype activity, especially on the VHF/UHF bands. It should help not only to get back some RTTYers who drifted off to play with computers, but also to stimulate some computerists to become hams.

The repeater modem translator described above has been in place since March, 1979. It is an inexpensive way to permit use of existing originate-only modems. ■

The Radio Shack Pro-2002 Scanner

—a look at the Shack's latest

When any manufacturer bills a new rig as the "ultimate scanner," naturally I'm skeptical. I've seen several of the new synthesized receivers which are promoted as being capable of receiving everything under the sun. They're usually rehashed versions of the lower-priced rf packages with some gingerbread knobs and switches added for color. These units are almost invariably full of bugs and prone to breaking down about one week after the warranty expires, so when Radio Shack announced the introduction of their new microprocessor-based scanner, I viewed it with anxious, but cautious, optimism.

The Realistic Pro-2002 is Radio Shack's latest addition to its line of scanners and is a replacement of the Pro-2001. It is cosmetically similar to its predecessor, being housed in the same-dimension case, but this is where the similarity ends. The 2002 is a totally new concept for Realistic and contains several features unique in scanner technology. The rig is microprocessor-based and all functions are accessed via the 30-key front-panel keyboard. It covers the 30-50 MHz VHF-low, 108-136 MHz aircraft, 138-174 MHz VHF-high, and 410-512 MHz UHF bands. Fifty channels may be stored in five banks of 10 each, as well as five search ranges, with individual delay, lockout, and priority options. Volume and squelch rotary controls are large and conveniently located. Logging indicators are provided for easy return to a desired setting. A 12-hour digital clock with am/pm indicator is becoming a standard feature in programmable units and is present on the 2002. Other useful functions are selectable scan/search speeds, directional search, scan and manual controls, external speaker, antenna, and tape-out jacks. A 120-V-ac cord is built in and a jack for 12 V dc is provided along with cables and mobile mounting bracket.

Due to the complexity and uniqueness of the Pro-2002, I will attempt to cover its features and functions individually rather than collectively.

Frequency Coverage

The 2002 has one of the most enviable frequency repertoires in the scanner industry. Bands covered are 30-50 MHz in 5-kHz increments, 108-136 MHz in 25-kHz increments, 138-174 MHz in 5-kHz increments, and 410-512 MHz in 12.5-kHz increments. That's a total of 4000 low-band, 1120 aircraft, 7200 high-band, and 8160 UHF channels, or 20,480 discrete frequencies! Notice that among these bands are included 138-144 and 410-420 MHz ranges, used by the US Government, which cannot be directly received by any other commercially available searching synthesized scanner.

Searching/Scanning Functions

A maximum of 50 channels may be programmed into the memory of the scanner. Channels are programmed into the unit via the 30-key color-coded front-panel keyboard and are stored in banks of 10 channels. These banks may be selectively scanned or locked out during scanner operation by using the appropriate bank-select key(s). Banks are labeled 10, 20, 30, 40, and 50. For example, bank 30 would contain channels numbered 31 through 40. In addition to storing channels to be scanned, these bank-select keys also perform double-duty as keys for selecting search ranges. Up to five ranges may be programmed into positions S1 through S5.

Both the speed and direction of the searching may be controlled. To initiate a search, the user enters the lower and upper search limits of the desired range and selects either the upward or downward direction. Direction may be changed at any time during the search. Search speeds of 3 or 8 channels/second may be selected by using a toggle-action push-button control. Once programmed, search ranges remain memorized even when the unit is turned off or unplugged, provided the 9-V-dc backup battery is installed. Ranges may be selected or locked out using the bank/search-select keys. If two or more search ranges are programmed and locked in, the microprocessor will search through all ranges sequentially. For example, if range S1 is programmed to search 154-158 MHz and range S2 is programmed to search 453-456 MHz, the unit will begin to search at 453 MHz after it has finished 154-158 MHz. If any other ranges are programmed and locked in, the searching will continue through these other ranges. Upon searching the last range in the sequence, the unit will repeat the search beginning at the first range. If only one of the five ranges is programmed, searching will repeat over this range only.

Scanning is controlled by using keys labeled scan, manual, delay, priority, and lockout. Manual channel selection may be achieved by either stepping through the channels with the manual key or by selecting a particular channel with the digital keyboard.

Lockout serves to eliminate a particular channel or channels from the scanning repertoire. Delay is used to add a three-second delay onto selected channels after a transmission is received and prior to the resumption of scanning. The priority key is used to assign priority status to one of the scanner's 50 channels. When a channel has been given priority, this frequency is sampled once every three seconds, for a period of 100 milliseconds, regardless of other scanner activity. If a signal is received during the priority sampling, the receiver immediately switches to this frequency for the duration of the message.

The scan rate is selectable at either 3 or 6 channels/second. For a rig with up to 50 channels to sample, this is too slow. Ideally, the rates should be selectable at either 15 or 20 channels/second. With the existing scan rate, however, I've found it to be practical to scan no more than 20 channels (two banks) at one time.

Miscellaneous Features

The digital readout display is comprised of seven-segment green LEDs and provides information concerning whether the unit is in the scan, manual, search, or program mode, if a channel is programmed with a delay or lockout, if the unit is in the priority mode, and which is the priority channel. Also indicated are which channel/search banks are active or locked out, channel numbers, and a seven-digit frequency readout.

The frequency display also doubles as the readout for the digital clock, indicating hours, minutes, and seconds. The clock, which operates in the 12-hour mode, requires continuous ac or dc current to operate. Should power be interrupted or cut off, the display continuously flashes "E00.00.00" until reprogrammed with the correct time. The clock cannot be programmed to automatically turn the scanner on or off at a desired time; it isn't a clock-radio.

Should the user desire to conserve power when operating the scanner from a battery, a switch is provided on the rear panel to disable the clock. The clock may be displayed anytime simply by pressing the clock key.

In order to stop the rig during the search mode, a monitor key is provided. This control also places a particular frequency from the search range into a special memory for future reference or transfer to one of the scanner's regular channels.

A mobile mounting bracket is provided in order to permit installation in a vehicle. A unique three-wire dc power cable is also included, consisting of black, brown, and red leads. The black cable is connected to negative ground and has an in-line connector for easy removal of the scanner. Red is connected to +12-V-dc continuous power source, and the brown lead is connected to +12-V-dc accessory fuse box terminal. (The purpose of the second +12-volt connection is for memory retention and clock circuits.)

A single external antenna terminal is provided, which is a decided advantage to the dual VHF/UHF inputs on previous Realistic models.

Rf Comments, Specifications

While the scanner is designed with both AM detection and FM quadrature detector, the two circuits do not function simultaneously on all bands. FM signals are received on all bands except the 108-136 MHz aircraft range, which is only received in the AM mode. The AM detector does not function on any frequency outside this band.

The Radio Shack Pro-2002 was added to its Realistic line of scanners this year and is a replacement for the excellent Pro-2001. While the 2001 covered only the conventional VHF-high/low and UHF bands (FM only) with 16 channels, it did so with overall sensitivity and audio clarity superior to the Pro-2002. On the specification sheets, both are listed as having the same sensitivity for VHF-high/low and UHF bands. In operation, however, the 2002 cannot receive and reproduce signals with the same clarity as its predecessor. Moreover, when field tested in mobile operation, the Pro-2002 had a high amount of static and ignition noise. Under the same conditions, the Pro-2001 received very little such interference. Another disturbing point is the reception of images and interference in the VHF-high band, especially in metropolitan areas with heavy signal density.

It is unfortunate that, with all the features the Pro-2002 includes, the rig doesn't have a better rf package inside. If its receiver circuitry performed as well as that of its predecessor, the Pro-2002 would be superb. Nevertheless, the unit's frequency coverage alone places it in a category by itself, and VHF-high band sensitivity is very good.

Should Radio Shack choose to re-manufacture the Pro-2002 and improve the VHF-high image rejection, UHF sensitivity, and scanning/searching rates, the results would be truly appreciated by serious monitor enthusiasts. Such a revamping was done by Radio Shack under similar circumstances with the DX-300 communications receiver.

The Pro-2002 programmable AM/FM scanning receiver is available from *Radio Shack, One Tandy Center, Fort Worth, TX 76102*. Reader Service number 479. ■

An Easy L-Meter

—you'll need a frequency counter

The measurement of small values of inductance often is difficult without specialized (and expensive) equipment. If, though, you have a frequency counter, a handful of commonly-available parts, and a bit of ambition, the undertaking is much simplified. If you have a simple calculator, the math takes only seconds.

The idea is not mine. It came from William Huffman N5CC, who asked me to prepare an article on the subject. Bill built the ancillary device to be used with a counter. The design is straightforward and its construction should present no problem. A glance at Fig. 1, which shows the schematic wiring diagram, will reveal a simple Colpitts oscillator.

This oscillator, which should have excellent short-term stability and good long-term stability, needs only the usual care in construction. The two fixed capacitors, constituting the combination reactance-dividing network and capacitance portion of the LC circuit, should be silver-mica or, preferably, polystyrene, for best stability.

As built by N5CC, the oscillator sits in a 12.5 cm × 8.75 cm × 7 cm (5″ × 3″ × 2.75″) cabinet. The Radio Shack 270-251 will give you room to spare. Internally, the 9-V battery shares space with oscillator components. Externally, the front panel holds a push-to-make momentary-contact switch and a pin jack for bringing out the rf signal. On top is a pair of binding posts for attaching the inductor to be measured.

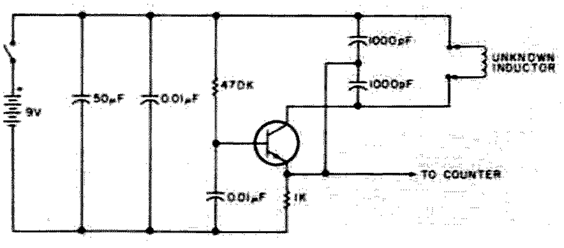

Fig. 1. Colpitts oscillator. Any high-beta NPN transistor should prove to be a reliable oscillator over a wide frequency range.

To use it, connect a counter to the rf output pin jack. Then calibrate the oscillator.

If you have an inductor of known value, this is a one-shot action. However, if you don't (and most of us don't), you can do a fairly accurate job by averaging a number of marked inductors. That's what I did. My hellbox delivered up a number of rf chokes marked 47 μH and 56 μH. In turn, each of these was attached to the inductor terminals and the resultant oscillator frequency was measured by the frequency counter. By presuming an accurately marked inductor, one can compute a presumed value for the internal capacitance of the oscillator circuit.

Average a stack of these and you have a figure that quite probably is reasonably accurate.

Here are the simple mathematical steps to follow in the computation of internal capacitance:

$$4\pi^2 f^2 LC = 1$$
$$C = 1/4\pi^2 f^2 L$$
$$C = 1/39.478 f^2 L$$

Let an inductor marked 47 μH be attached to the oscillator and the resultant frequency be recorded (in MHz). Presume it to have been 1.032 MHz. Then, to have capacitance ascertained in picofarads, CpF = $1/39.478 \times (1.032)^2 \times 47 \times 10^{-6}$
$= (1 \times 10^6)/39.478 \times 1.065 \times 47$
$= (1 \times 10^6)/1976$
$= 0.000506 \times 10^6 = 506.$

Repeat this operation for a number of marked inductors and then average the results. In my case, the average was very close to 500 pF, which seemed to be a

reasonable value considering the components in the oscillator circuit.

Going back to our original formula and using f in MHz, L in Henrys, and C in picofarads, we see that:

$L_H = 1/4\pi f^2 C$
$L_H = 1/39.478 f^2 500$
$L_H = 1/19739 f^2$
$L_H = 0.0000506/f^2$.

Now let's put an inductor marked 56 µH, 5%, in the oscillator. Its frequency measured 0.9648 MHz. Dropped into the formula:

$L_H = 0.0000506/(0.9648)^2$
$L_H = 0.0000506/0.9308$
$L_H = 0.0000543$
$L_{\mu H} = 54.3$

If we presume the inductor was correctly marked, the accuracy of the formula is confirmed. All you need to remember for future measurements is one concise formula:

$L_{\mu H} = 50.6/f^2_{MHz}$.

There are a few precautions to be observed. The lead from counter to oscillator affects frequency, so it should be precisely the same from calibration to use.

The developer, N5CC, recommends that several oscillators be used for enlarging the range of inductors to be measured. His prototype, which has 1000-pF capacitors in the LC circuit, works best in measuring low-value inductors. He suggests the use of 10,000-pF capacitors for inductors in the 1-mH to 1-H range.

Note that the accuracy of inductor measurement hinges upon two factors: the accuracy of the frequency counter and the precise knowledge of the calibrating inductor. The former should present no problem, but finding an inductor of an exactly-known value is not easy! Take consolation in the fact that its use is required only once! ■

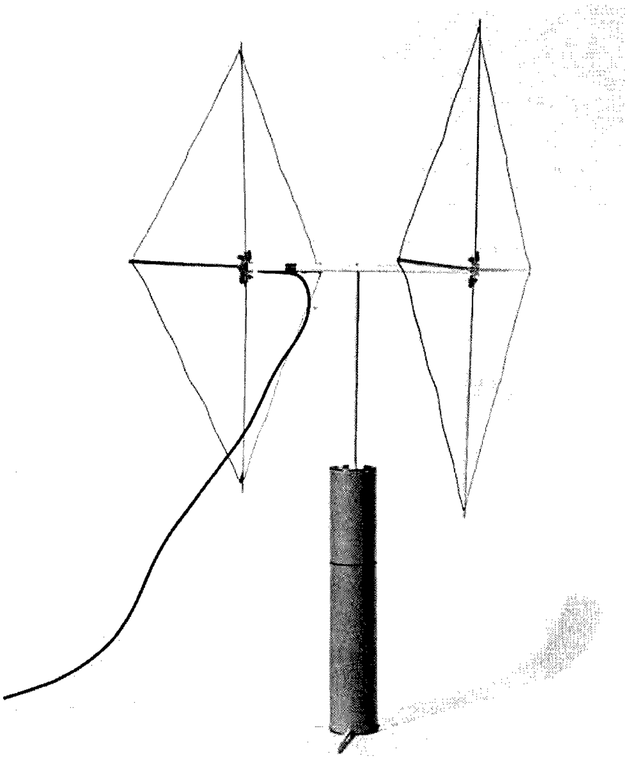
A Quad for Two Meters

—the Palomar portable power picker-upper

For the most part, we take the ease and convenience of two-meter FM operation for granted. Since it's possible to access a repeater in many areas with almost no antenna, there's a tendency to let the repeater do *all* the work, just getting by with an absolute minimum for a portable or mobile antenna—rubber duck, quarter-wave whip, or the like. This approach works most of the time, allowing casual operation through repeaters, but often falls far short of providing really good performance when working simplex and when used under demanding conditions of rough terrain, contest competition, and poor propagation paths.

If your fancy turns to backpacking, mountaintopping, and similar ham pursuits, the added forward gain and physical selectivity offered by a small beam will reap handsome dividends. Most apparent will be the improvement in transmitted and received signal levels, but—very important to whose who regularly operate from the higher elevations—the "physical selectivity" (front-to-back and front-to-side discrimination) offered by a beam will make such operation a great deal more orderly, reducing the tendency to key up several repeaters simultaneously and sorting out signals on the popular simplex frequencies. One of the most suitable antennas to do these things is the quad.



Portable two-meter quad from Palomar Engineers.

The quad is primarily considered an antenna for the HF bands, with its asserted element-for-element superiority over the yagi and its potential for use of low-cost construction materials. But the quad is a good performer on any frequency, and in recent years has received increasing attention as an effective and efficient VHF and UHF antenna.

There are a number of reasons for looking at the quad for VHF/UHF use. The antenna can be built of inexpensive and easily-obtained materials, and its performance can be equal to or better than other arrays of comparable size. Adjustments for resonance and feedpoint impedance matching are easily made, and the antenna readily lends itself to stacking either side by side, or one above the other, as with yagi arrays. Too, the quad is a relatively broadband antenna, making it particularly useful on the wider VHF/UHF bands.

The basic quad consists of a full-wavelength driven loop and a reflector, which is cut about 5% longer than the driven element and spaced between 0.15 and 0.25 wavelength. Closed loops can also be used for the directors, in which case they are made 5% shorter than the driven element. Any reasonable number of directors can be added, until the antenna becomes too bulky and unwieldly and a point of diminishing returns is reached.[1]

As a rough guideline, when compared with the half-wave dipole, the two-element quad shows a gain of 6-7 dB, as opposed to a 5-dB gain for a two-element yagi. The three-element quad (reflector, driven element, and one director) is capable of about a 10-dB gain, while a five-element quad—generally considered impractical at HF frequencies except by the hardiest "antenna farmers"—checks in with a gain of 13 dB.

[1]For a specialized discussion of the quad on the higher bands, refer to the RSGB *VHF/UFH Manual*, by D.S. Evans G3RPE and G.R. Jessup G6JP. A British publication, the book is readily available in the United States.

Besides the plain-vanilla quad, there are several specialized configurations popular on VHF and UHF. The so-called Swiss Quad, pioneered by HB9CV, is an all-metal, mechanically-excellent, all-driven array having a radian pattern comparable to that of the ordinary quad. The expanded or bi-square quad is a takeoff on the basic configuration, in which dimensions are expanded to two wavelengths for each loop (for added gain); dimensions are still practical even on the lowest VHF band, 6 meters. The Super Quad describes virtually any combination of standard (one-wavelength) or expanded (two-wavelength) quads stacked in various arrangements to yield very high gain figures. Finally, the Quagi, which is a hybrid antenna blending features of both the quad and yagi into a single design, uses a standard one-wavelength quad driven element and reflector in combination with dipole (yagi) director elements. The result is an antenna boasting high gain, simplified construction, and easy feedpoint matching.

Regardless of type, simple quads scaled to VHF and UHF dimensions are increasingly popular in mountaintopping, Field Day, backpacking, and portable operation for reasons of economy, bandwidth, high gain, portability, and relative ease of construction. An interesting commercial two-meter portable unit—perhaps the first commercially produced—is the Palomar Engineers collapsible quad. Designed particularly to extend the range of low-power two-meter transceivers by providing the gain and front-to-back discrimination of the two-element quad, it is a good candidate for serious in-the-field work when one would like to have the effective gain of a linear amplifier but without being saddled with additional battery power and weight requirements.

The Palomar design is based on one of the several portable quads described by R.J. Decesari WA9GDZ/6 in the September, 1980, issue of *QST*.[2] The Palomar antenna, presented as a good alternative to a standard 4-element yagi, is capable of up to 6 dB forward gain with an excellent front-to-back ratio.

The original WA9GDZ/6 designs were the results of a quest to construct a highly portable (non-yagi) antenna that packed a substantial gain into a small package; efforts to design a collapsible yagi had proved overly large and cumbersome. Several alternative designs were built, some with 45-degree diagonal polarization for good compatibility with both FM (vertically-polarized) and SSB/CW (horizontally-polarized) modes, and some with straight vertical polarization. Other models were built that used different methods of keeping the quad spacers erect. The Decesari antennas can be made from any of several hardwood, plastic, and Plexiglas™ material; the loops are constructed of copper wire.

Palomar Engineers are the exclusive manufacturers of the patented 2-meter version, which is based on the Fig. 7 design in the *QST* article.

The antenna uses quad driven-element, reflector, and spacing dimensions optimized for 146-MHz operation, with the feedpoint at one side of the driven element to yield a vertical polarization characteristic for FM work. These figures work out to a driven element about 1.72′ on a side, a reflector 1.80′ on a side, and an element spacing of about 16″. In this design, the elements are made of #18 PVC hookup wire, the quad "spider" is lucite, while the spacers, boom, and mast are of wooden dowel construction. The storage container/support is fabricated from cardboard and has a varnish coating. The antenna uses knurled brace thumbscrews to hold the spacers in place. Four wooden spokes at the bottom of the storage container form a stand to provide support for the antenna, both to keep it steady and to prevent its blowing over (mountaintopping, you know!). To aid in 50-Ohm feedline matching, a matching stub and trimmer capacitor are provided.

At present, the antenna is sold fully assembled. According to Jack Althouse K6NY of Palomar Engineers, they plan to furnish them unassembled in the future. Also expected are some changes in mechanical details to lower the cost.

We found the antenna to be an ingenious one, certainly worth consideration by the serious backpacker, to whom *portable* means just that. When collapsed, the antenna folds completely into the storage container/support tube, with the spacers folding along the longitudinal axis of the boom. Overall weight is but 1-1/4 pounds. We did consider the antenna stand to be a bit on the fragile side, so one must take care in carrying it, in its installation, and in its use.

Although rigorous antenna pattern and gain tests were not performed, the portable antenna exhibited a marked forward gain and front-to-back ratio. These characteristics were clearly evidenced when working through repeaters outside the local area, where rotating the antenna produced the anticipated signal strength changes. The quad antenna's superior performance was quickly noticed when making comparison checks between it and a 5/8-wave whip, when driven by a two-Watt handie-talkie (HT). When using several repeaters 25-35 miles distant, the HT-mounted 5/8-wave resulted in marginal performance on both transmit and receive, while use of the quad made operation into several of these repeaters almost full quieting. When the quad was compared with the HT's stock rubber duck, there was hardly any comparison at all: Some repeaters that were marginally readable on the rubber duck were very nearly full quieting, and it was often possible to access machines that were unusable before because of inadequate signal strength from the HT.

What about swr? We found that the standing wave ratio was quite acceptable across the entire frequency range covered by the antenna. Swr at the design center frequency of 146 MHz ran about 1.1:1 and changed almost imperceptibly over the 144-148 MHz range. These measurements were made without any pruning of the antenna or adjustment of the matching stub. Being very broadbanded, it's unlikely that any adjustments would have to be made.

We found the little quad to represent a novel idea as far as VHF antennas go. It's a highly compact but practical package especially suited for on-the-go operation. Perhaps a bit dear at $87.50, but with the price subject to downward revision when the antenna becomes available as a kit, it's a very nice range-extending accessory to have and use.

Who says hiking can't be fun?

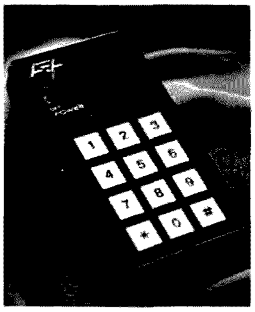
INTIMIDATED BY MORSE CODE?



THE NEW AEA MODEL MT-1 COMPUTERIZED MORSE TRAINER MAKES MORSE CODE EASY AND FUN TO LEARN.

KT-1 Computerized Keyer With All Features of Above Trainer is Also Available in Same Package

- Automatic Speed Increase, User May Program: Starting Speed, Ending Speed, Practice Duration; 5 Letter code Groups or Random Space; Common or All Characters.
- Precise Speed Control 1 to 99 WPM (Tailor to Your Exact Requirements).
- 24,000 Character Answer Book Available For 10 Starting Positions.
- Random Mode For Practice (No Answers).
- Operates from 12 V.D.C.

"Chopstick" Helical for 432

—satisfies your Phase III appetite

Forward gain, forward gain: that's the ceaseless search in satellite work. It's a task that jumps to the forefront with the approach of a new breed of satellite—Phase IIIB.

The Phase IIIB satellite will be put into a "pseudo-synchronous" orbit—which means that it will offer many of the advantages of commercial synchronous satellites. It will swing around the bottom of the globe at a low perigee of 1500 km and then hurtle out to an apogee of 36000 km—and (here's the bonus)—its movement relative to an earth station for the 4 hours spanning this apogee will be small. For four hours there will be an almost-stationary satellite up there, covering half the globe.

For the first time, radio amateurs will be able to communicate on a worldwide basis using VHF + UHF, thus skipping many of the baneful problems of HF propagation. What's more, Doppler shift at the apogee will be very slight—so that the skillful searching and re-tuning so essential with low-orbit satellites will no longer be required.

But there is a price to be paid for these advantages! Path length at apogee is virtually the same as that for commercial synchronous satellites. While they counter this path loss by using giant 30-metre dishes and low-noise amplifiers on receive, cooled in liquid helium, no amateur can compete with this! But latest estimates for Phase IIIB suggest that we can get by with an erp of 500 Watts—a tolerably modest figure. Of course, a 500-Watt final is out of the question for most amateurs—so we have to get our gain elsewhere—notably from the antenna system.

Phase IIIB uplink will be centered on 435.215 MHz and will require clockwise circular polarization. So—how to make a high-gain antenna with circular polarization which can be hoisted into the air and pointed in the right direction without too much trouble? That is the question.

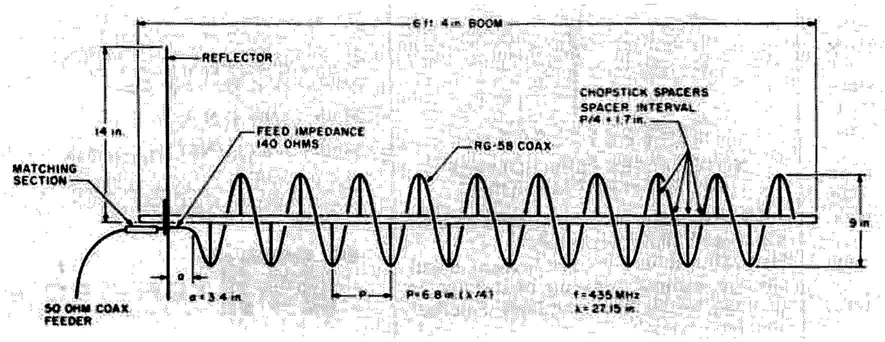

Fig. 1. Ten-turn "chopstick" helical: gain 15 dB, beamwidth 36 degrees.

Long-John yagis—crossed and phased—could offer one solution, but at 435 that phasing harness could present problems, while impedance matching is also a chore.

So, why not a helical? Here we have neatness, high gain, wide bandwidth and circular polarization—all in one. Scanning the handbooks for design info on helicals showed that a ten-turn helix looked promising: a gain of 15 dB would persuade my 10-Watt output to masquerade as 300 Watts, and a beamwidth of 36 degrees ought not to be too finicky to point. The boom length at 435 MHz would be about 6 feet, with a reflector 28 inches square—these seemed manageable dimensions. But what to use for the helix, how to form it, how to keep it in shape? All pertinent questions at this particular QTH—with the nearest parts or material stores some 70 miles away.

The boom was no problem. A 6'4" length of 1"×1/2" meranti timber, good and straight, looked just about right—with the 1" edge vertical to avoid

any bending (as it happened, the antenna itself turned out to be featherlight and easily supported by the 1″ × 1/2″). But what about the helix, and what about the spacers?

Copper tubing was unobtainable; in any case, it would have been expensive, heavy, and difficult to shape. Someone, somewhere had mentioned using coaxial cable: so why not RG-58? The outer screen would simulate a tubular conductor; the inner conductor is not needed but could be soldered to the screen at each end. Good grade coax has a tinned, close-mesh screen with an excellent weatherproof sheath. What could be better? I promptly hunted out a 25-foot length.

Spacers were now the problem. Most handbooks showed 3 spacers per complete turn of the helix, each spacer being set at a 120° angle to the last. Since the boom was rectangular, it seemed more sensible to opt for 4 spacers per turn, and to put them at 90° settings. The original plan was to use 1/4″-diameter plastic rod or wood dowel for the spacers, but nothing remotely resembling such material was available locally. Pondering the problem over a tasty meal of Fuyong egg, crispy chicken, and Cantonese bean curd, I suddenly saw the answer there in my right hand: chopsticks! Why not?

Chopsticks are available in a wide variety of designs and materials in Malaysia. I chose simple, wooden, everyday chopsticks (not bamboo)—undecorated—sold in bundles of 20 for 25 US cents a bundle. As with most chopsticks, the lower half has a circular, tapered cross-section, merging into a rectangular shape for the upper half. It couldn't be better! I marked the boom at 1.7″ intervals and drilled holes 3/16″ in diameter—consecutively at right angles for its entire length. The boom was long enough to allow 3 to 4 inches to stick through the reflector, for clamping purposes. A 3.4″ piece of the same boom material was fixed to the boom at the reflector end, and the 1.7″ intervals were measured from this. All this can be seen clearly from Fig. 1.

A drop of glue was put into each drilled hole, and the chopsticks were pushed in one by one until they wedged tight. A double-check made sure that they were put in with a clockwise spiral, as viewed from the reflector forward (that is, from the back of the beam). When giving the final push, each chopstick was twisted so that the square sides were roughly in line with the path that the RG-58 helix would take. This made it easier to file a small U-shaped depression in the top to allow the RG-58 to sit in neatly.

Chopsticks are generally about 10 inches long, and when pushed through the boom about 4 inches protruded on the other side. These bits were carefully sawn off. The helix diameter is 9 inches, so a mark was made on the last 4 spacers at each end of the boom, at a point 4-1/2 inches from the center line of the boom. A fine hole was drilled at these marker points and thread strung along from first to last spacer in each of the 4 rows. This enabled the other spacers to be marked to show where they should be cut off.

After trimming, the tops were filed into a U-shaped depression in line with the helix path. A small hole was then drilled, an eighth of an inch below the tip, so that a piece of waxed thread could be used to bind the RG-58 helix in place.

One end of the 25-foot length of RG-58 was bared for half an inch, the sheath and dielectric removed, and the screen and center conductor twisted together and soldered. Starting with this end, the RG-58 was bound to the short, straight, end section (3.4 inches) next to the reflector position. The soldered tip was placed so that it would mate with the center terminal of an SO-239 socket which would be mounted on the back of the reflector. The RG-58 helix was then wound carefully around the spacers, one at a time, binding in each spacer before moving to the next. In this way it was possible to ensure that an even, circular spiral was created—with no bulges or flat sections. As we neared the tenth turn, there was about 8 inches of surplus RG-58. This was cut off, the end trimmed, and the outer screen and inner conductor were soldered together as at the start of the helix. The thread bindings were touched with glue, and the boom and chopsticks given a coat of clear varnish and set aside to dry.

Colin Richards 9M2CR with the completed project.

The helical at work—note that the reflector frame is now a lightweight bicycle wheel rim, which is "neater, lighter, and better looking."

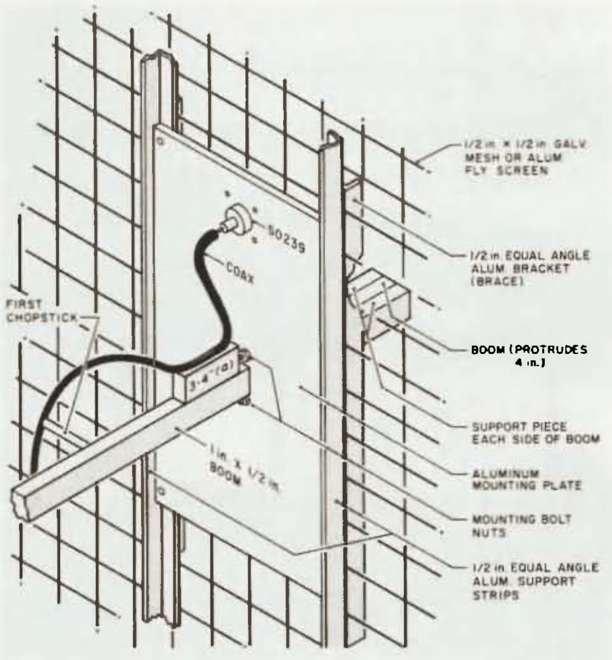

Fig. 2. Front-view details of mounting the bracket on the reflector.

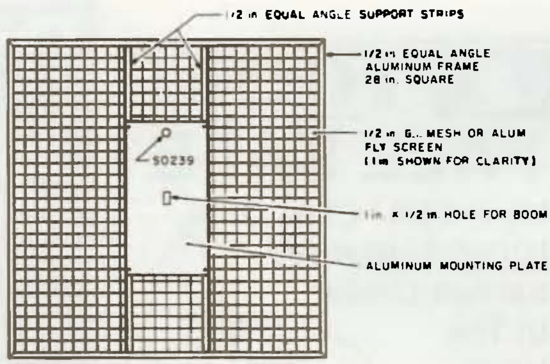

Fig. 3. Details of the reflector.

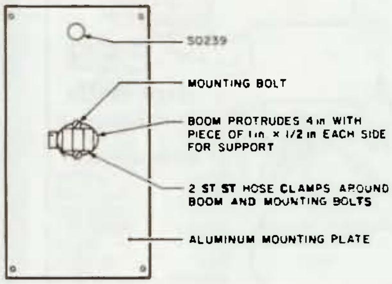

Fig. 4. Back view of the mounting plate.

The reflector came next. (Note the later improvement in the photo of the helical at work.) Half-inch-squared mesh GI screen was used, and a 28-inch square cut out and edged with 1/2″× 1/2″ aluminum angle. A small, sturdy aluminum plate was used as a center mount for the reflector (it was, in fact, an old door-lock plate!). An aperture 1″×1/2″ was cut in the center to allow the boom end to fit through and protrude 4 inches on the other side of the reflector. Above and below this aperture a hole was drilled for a 3″×1/4″ carriage bolt. The bolts were firmly screwed to the plate, with most of their length also protruding to the rear of the reflector.

Two more lengths of aluminum angle (1/2″×1/2″) were screwed across the plate in a vertical direction, to make the reflector rigid. The SO-239 socket fitted to the plate, facing rearwards, with its center terminal lined up with the end of the helix at section A in Fig. 1. The antenna boom was then pushed through the reflector mounting plate, carefully squared up, and fixed firmly in place with two stainless-steel hose clips around bolts and boom.

The reflector weighed about 8 pounds, whereas the antenna-plus-boom was only 2 pounds. A plywood bracket was therefore fitted at the balance point, just a few inches from the reflector. Minor dents in the RG-58 helix were pushed gently into shape, and the ten-turn "Chopstick" helical was ready for hoisting aloft! Almost ready, that is.

Securing the boom to the reflector.

The helix attached to the "chopstick" spacers.

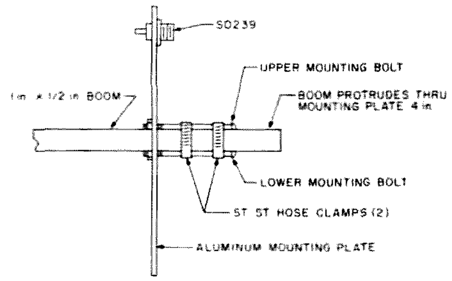

Fig. 5. Side view of the mounting plate.

There still remained the question of matching to a 50-Ohm feeder. The feed impedance of a helical antenna of this design is near enough 140 Ohms (this stays the same, by the way, regardless of the number of turns in the helix). A quarter-wave matching section should therefore have an impedance of about 84 Ohms. The nearest coax is RG-62, which has an impedance of 93 Ohms. A quarter wavelength at 435 MHz is 6.8", and the velocity factor brings this down to 5.7" (there's a trap here: solid dielectric coax like RG-8 or RG-58 has a velocity factor of 0.66, but is partly air-spaced and the factor is 0.84). After many "cuts and tries," the swr was brought down to 1:1.1. So this time the antenna was really hoisted in the air and put to work. Results? When used as an uplink antenna on OSCAR 7, Mode B, signal reports have been encouraging; downlink on Mode J, I can copy stations right down to the horizon. I think it works! ■

The Code Pet

—a Morse tutorial for Commodore's computer

Alden Lansdowne AAØG
335 North Vassar
Wichita KS 67208

You're practically a shoo-in for that upgrade license if you can copy the code from this program written for the Commodore Pet™. You pick the speed from five to twenty words per minute and it sends perfect code in groups of five characters. Since this is a sound program, you will need an addition to the Pet such as can be found in *Kilobaud Microcomputing*, March, 1979. The article by Gregory Yob on page 71 explains several ways to connect sound. I strongly recommend the method in Fig. 4(b). By the time I isolated an amplifier with capacitors, I had distortion. The transistor seems to be best and also is easy to construct.

After you enter the speed, the screen is blanked and you copy the code with pencil and paper as you would if you were performing for the FCC. After 100 groups of five characters (or five minutes), the screen will show the text sent. A completely random text of letters, numbers, and common punctuation will assure you of receiving all characters equally.

Should you wish to stop before the computer is finished, type S and the computer will respond. Code is sent as near the input speed as possible for me to program. (If you make improvements, please let me know.) The basis for the time was reached by running the program, timing for five minutes, and then counting the groups of five characters. Speeds under 13 words per minute are sent at 13 words per minute with additional

Program for Morse code.

spacing between characters. The timing for this is accomplished in lines 220 through 240. Line 270 is incomplete, but before the screen is turned on, line 610 will finish the sentence and tell you how many groups you have copied. Line 290 includes an extra POKE statement; however, without it, you would hear a false tone the first time you ran the program.

This program uses the inherent ASCII code in the Pet to reference a number to the corresponding ASCII character for display. Line 320 removes the holes in the ASCII code. Line 300 follows guidelines for sound pitch as in *Kilobaud Microcomputing*, February, 1979, page 9. If the tone is not right for you, change the 211 in line 420 to any number between 1 and 255.

Line 600 turns the sound off. If you have inadvertently pressed STOP, just type RUN 600. You won't see it on the screen until you have pressed RETURN. The program as shown will run until 100 groups have been sent. If you want to copy for only five minutes, add line 205 and change line 560 as in Version II.

Learning code isn't always that much fun, so anything to ease us through this period helps! Good luck on the upgrade. ■

No More Two-Tone Sidetone

—modify your AEA keyer

The AEA CK-1 and MM-1 are spectacularly versatile keyers, and after many months of using both of them I have only one complaint, a complaint that many others have voiced. The problem involves the sidetone.

Let's face it—there aren't many keyers with a nice smooth sine-wave oscillator for the sidetone. On the other hand, most transceivers offer excellent sidetone characteristics. Moreover, when using the transceiver's sidetone, you can avoid the embarrassment of having the keying cable go bad while you are sending, or (heaven forbid!) forgetting to flip the "transmit" switch. In both cases the sidetone on your keyer would percolate along happily, giving no indication of the fault.

So what's the problem? If you want to use the sidetone in your rig rather than the one on the keyer, you can simply turn down the volume control on the keyer, right? Wrong! If you turn down the volume control on the keyer, you won't hear the audible confirmation of each entry you make on the AEA's keypad. This can lead to errors in message loading and speed selection if you don't depress the keys firmly, or there is keybounce.

The solution is ridiculously simple. Unlimber your soldering iron, and in less than five minutes you'll have your AEA keyer giving you audible confirmation of entry, but no sidetone. We'll start with the CK-1, since that keyer is nearest and dearest to my heart.

Remove the two screws on the sides of the keyer and carefully separate the two halves of the keyer. On the circuit board, locate diode D1, which can be found next to U3, just south of the 7805 regulator. Check the pictorial in the manual if you are not sure that you have the right one. Now here comes the hard part. Brandish your soldering iron threateningly before the keyer, and then unsolder one end of the diode. That's it! Tape the diode so it doesn't short out anything, and close up the keyer.

The MM-1 is equally simple to modify. The diode of interest in the MM-1 is the D1, located near the crystal. There are two diodes and a resistor in a row; the diode you're after is the second one from the resistor. Unsolder one end of the diode, and you'll have verification of key closure, but sidetone only from the rig.

If you wish to use the keyer's sidetone from time to time, you can simply install a miniature SPST toggle switch to switch the diode in when you want to hear sidetone from the keyer. In the MM-1, the switch can fit in one of the holes drilled for the Aux jacks. Space in the CK-1 is a little tighter, so you'll have to drill your own hole, but there is still plenty of room. ■

Monodes

—harbinger of a new age

Everyone has doubtless heard, at one time or another, that there lurks at the far fringes of electronics an engineer's unicorn or will-o'-the-wisp known as the monode. Most of what you have heard is humorous and misleading in nature; this is simply a cover for a lack of hard facts.

But with recent developments promising to catapult it squarely into the limelight of the next wave of innovation, it has come time to broaden its acquaintanceship. Engineers and hobbyists alike stand to benefit greatly. Both will find the new information of prime interest. We will now proceed to unburden the monode of its undeserved myth of uselessness.

Monodes have left their mark through much of early history. This fact is now clearly seen from the new perspectives given to us by contemporary historians of technology, notably Y. Coyle Dunbar-Dexter and Isadora Pisa Ferniccia. Specimens of early ones range from bits of copper embedded endwise into clay beads (Chichen Itza, Angkor Wat) to bronze pin-shaped leads in wooden beads or buttons (Gizeh, Jericho). Fig. 1 shows representative pieces from these sites, circa 2240 BC to 1680 BC.

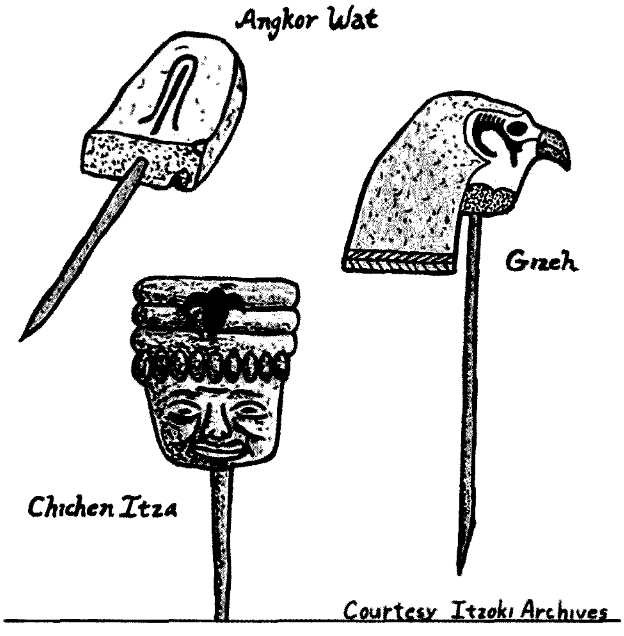

Fig. 1. Representative ancient monodes.

This graphic argument needs no further justification. The ancients' failure to extract a usable performance from them, however, led to their continual burial and rediscovery in widely scattered places and times.

There are historians who scoff at the ancient monodes theory, nonetheless. Most often, these are not technically oriented people, and so they put forth the rather tepid counter that the so-called monodes are often found in proximity to such commonplace articles as combs and brushes (who among the present readership has not built a Wimhurst or Van de Graff machine?); some are even found right in a mummified corpse's hair!

We can scarcely blame the ancients for burying these defiant devices with their frustrated and no doubt defamed inventors, perhaps wishing both a kinder break in the afterworld.

In point of fact, Puck's Staff, as we might well call it, had been a thorn in many a Skyptickal Experimenter's side all through the Renaissance, as well. The first relatively modern mention of them is found in a rough draft of a never-finished monograph, as it identified itself, by Evangelista Torricelli, in 1642. Fig. 2 shows this work. He had a vague notion that the strange forces found in amber, animal fur, and the like had an affinity for metals and proceeded to tackle electrode theory one electrode at a time.

Since an electrode's principal characteristic seemed to be its length, he assembled one by putting mercury in a glass tube and inverting it into a shallow dish of more mercury. This was to provide an easy means of varying its length, but he became so engrossed in the tricks the atmosphere played on it that he dropped further dead-end research in favor of the easier quarry. He invented the barometer the following year as a result.

Benjamin Franklin also delved into the matter for a

time. This has been determined by piecing together scattered interviews biographers held with younger contemporaries after his death. Franklin mounted ball-capped rods atop Leyden jars (the now-familiar ball and stem most static electricity devices sport), but found that, when capped with wooden or gutta-percha insulators as monode theory calls for, they became quite refractory to further experimentation. He, too, gave up in despair. Fig. 3 shows this relic of the lackluster side of science.

Many nineteenth century luminaries also wrestled with the "wicked one-legged beastie," as Samuel Morse referred to it. But, with so many highly successful endeavors proceeding forth, this was scarcely a time for championing the lame ducks of technology.

Michael Faraday attempted to derive the form of the Tubes of Force he would find around a monode. His subsequent nervous breakdown forever sealed off any chance of knowing just how close he may have come to the truth of the matter. He became so distracted that he could only talk about irrelevant trivia for years, never touching on the subject for a moment. Research is also in progress on the so-called heavy metal poisoning that afflicted Isaac Newton.

Heinrich Hertz came much closer than anyone to seeing the monode in its own right. He attempted to ascribe to most common arrangements of matter a "monopolar character" to account for the apparent lack of omnipresent electromagnetic activity as observable in his day. He was right, in that monodes do *not* make antennas, and vice versa. We will go into this in more detail.

As twentieth century physics unfolded, portraying a world in defiance of common sensibility, the monode began to fall into line as a viable entity in its own right. Engineers and scientists here at Bull Laboratories have detailed its operating principles, and applications research is in progress at a rapid pace, aided by the sophisticated support technologies available today.

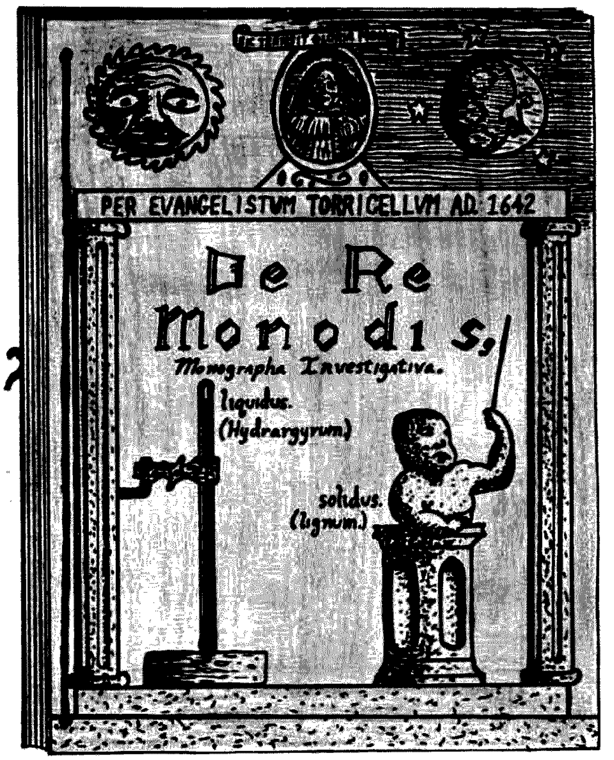
The basic stumbling block all along has been in the current mode assumed. Both monodes and superconductors, therefore, exhibit essentially surprising behavior in the macroscopic realm.

Rather than burden the reader with quillets of theory, we will here take the more pragmatic and intuitive approach and describe the appearance and measurement of basic monode circuit parameters:

Voltage—Voltage is a measure of electromotive potential difference between two points. The voltage of a monode with respect to any other point in a circuit can be measured readily enough, but the one-lead device cannot have a voltage drop as such. Monodes do not *drop* voltage, so much as they never *pick it up*.

Current—Current does not flow in monodes in the conventional sense. Kirchoff's Law still applies, however. The monode's voltage with respect to any other point in the circuit remains constant as long as currents flowing into the monode are equal in magnitude to the currents flowing out. The fact that both flow over the same lead simply means that conventional current meters register nothing.

Resistance—Since this is defined as voltage drop per unit current, we have a double dilemma, as witnessed



E.F. Bull-Private Collection

Fig. 2. Torricelli's investigation.

above. Is the monode's behavior independent of the resistivity of its conductor? Does it display a temperature coefficient of some sort? And what about heterojunction effects? One might well ask.

Ac measurements are also difficult. Since there is no externally definable current, how can it alternate? Ac monodics seemed a doomed cause until the invention of the alternating source in 1936 by Bull Laboratories founder General E. Fuller Bull. See Fig. 4 for operating details. Shown in the inset is a modern equivalent—an array of series connected photovoltaic cells is illuminated by an LED and mounted on a quartz crystal which is made to oscillate by a conventional oscillator circuit.

You might now see why Hertz' original notion about ac and monodes is true. If we try to make a monode antenna, say, by topping an automobile radio antenna with a decorative foam ball, we are in reality going to be receiving signals from the lower segments of the antenna, which act as unshielded conductors from the radio's coax connector to the top segment. It is this top segment which, together with the foam ball, forms the monode. Hoping to force the top segment to become a monode/antenna by removing the lower segments is of no use. Now, the lower half of this segment is needed to connect the upper half (the new monode) to the coax connector. It is this new unshielded conductor, of course, which picks up signals. Chopping away until only the foam ball remains, we at last see how poorly monodes func-

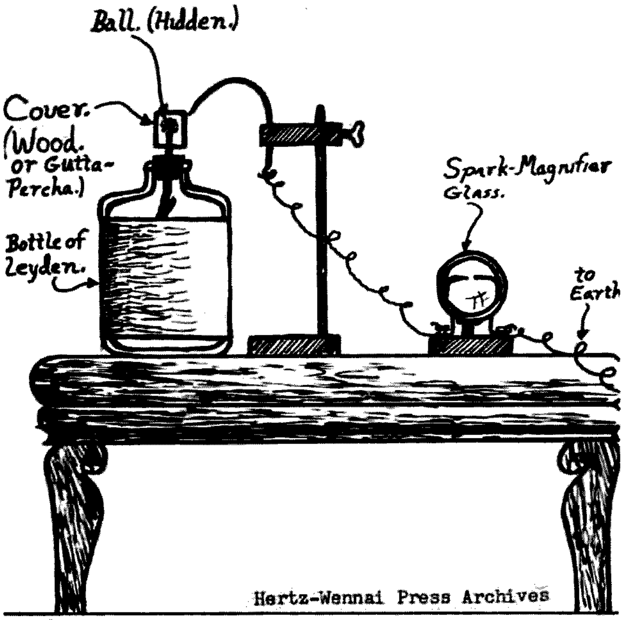


Fig. 3. Franklin's monodick apparatus.

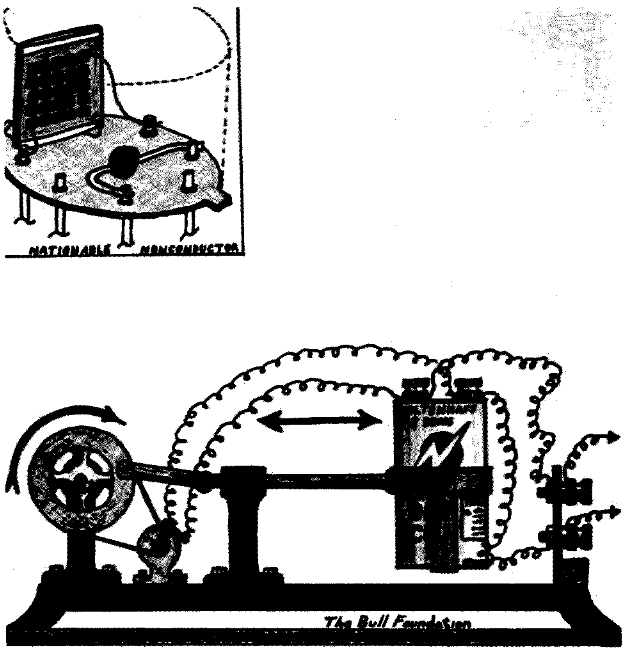

Fig. 4. Early and modern alternating sources.

tion as antennas.

The monode will see its first gamut of applications in the digital field, owing to its highly unary truth table and singularly consistent characteristics. Indeed, Buckminister Fuller has dubbed the monode "the unit of electrical behavior."

As an example of its almost trick logic, note Fig. 5, the data bandwidth doubler. This feedthrough device is crimped onto stranded hookup wire to increase its pulse bandwidth and functions as follows:

Logic ones are conventionally communicated as current pulses. (Complementary codes exist, too; we will stick to this one for simplicity.) These pulses obviously must flow over the low-resistance path offered by the wire. Logic zeroes, on the other hand, are represented by an absence of current and thus obviously prefer the *high*-resistance path formed by the two 100-megohm resistors in series, which prevent their being swamped by ones. Since negligible current flows over this path, the two monodes terminate the path at source and destination for a healthy cost and weight savings over twisted pairs or coax.

Monodes now largely use standard integrated circuit technologies owing to their availability. However, new and more appropriate variants are appearing, notably SEAMOSS (Superinsulating Epoxy And Metal Or Substantial Substitute), based on the valence-filled NC (no connection) junction.

Since monodes do not use conventional current, it must be bypassed. This was done at first in the power supply, using a hefty shunt resistor and an air gap or glass rod in series with the output.

The development of the powerless monode did away with this, however. This three-terminal device, in addition to dissipating heat from the bypassed current, also dissipates "peat," or powerless heat, the zero-energy equivalent of heat dissipated by conventional current. Thus, in addition to being mounted on an aluminum heat sink with silicone grease, the device must also be attached to a transite pad with asbestos grease, for peat's sake.

An even more recent development, allowing monode ICs to be used in conventional circuits, is the incorporation of bypass resistors into the IC case. These damp supply line ripple as an added benefit, since often they have values on the order of .03 Ohms or less.

The first digital monodics research was done in 1967. A team of Bull Laboratories scientists theoretically predicted the properties of a monode gate which they proposed to call a "dislatch." Upon fabrication and testing of the first unit, however, it was deemed a flop.

There are two kinds of flop, J and K, which are identical, which is simply to add variety to texts on monode theory and practice. Much of this would be stodgy pottage, indeed, without such details; the phenomenon is known as "monotony."

The flop possesses a unique ability to keep circuit complexity to a minimum. This is due to the fact that the output is independent of the input, folding its truth table down to a mere speck of ink on the printed page and making it highly noise-immune as well. The distinction between ripple-through and synchronous logic becomes superfluous.

Some digital functions served exclusively by the monode and its MSI derivatives include the Gunn Effect No-Shot Schmitt Trigger; its output is a blank when it is not loaded.

The flop is also the ideal matrix element for the WOM or Write-Only Memory. Far from being the white elephant many wags have painted it to be, it finds many useful applications. It is usually functionally organized as a set of interpenetrating spirals to form a circular file or data sink.

One use, which may have far-reaching consequences, is in the capacity of a data terminator. Not knowing the inherent capacity of the Bit Bucket, which we must assume on thermodynamic grounds to be finite, it is wise to provide for the dis-

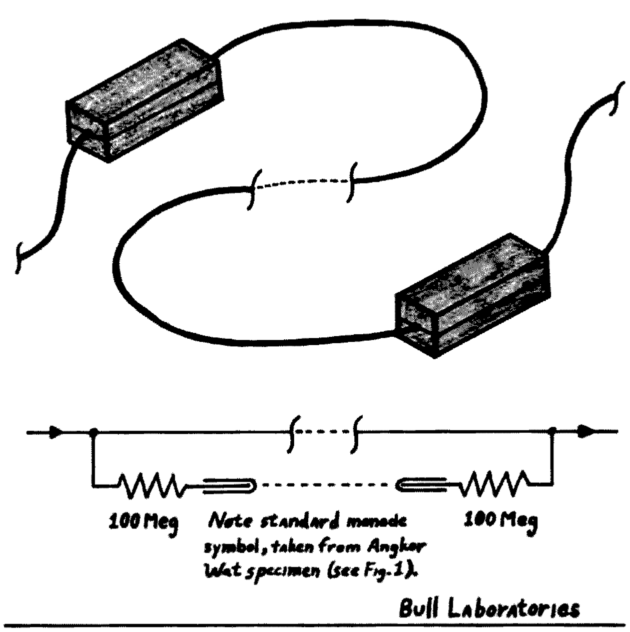

Fig. 5. Data bandwidth doublers.

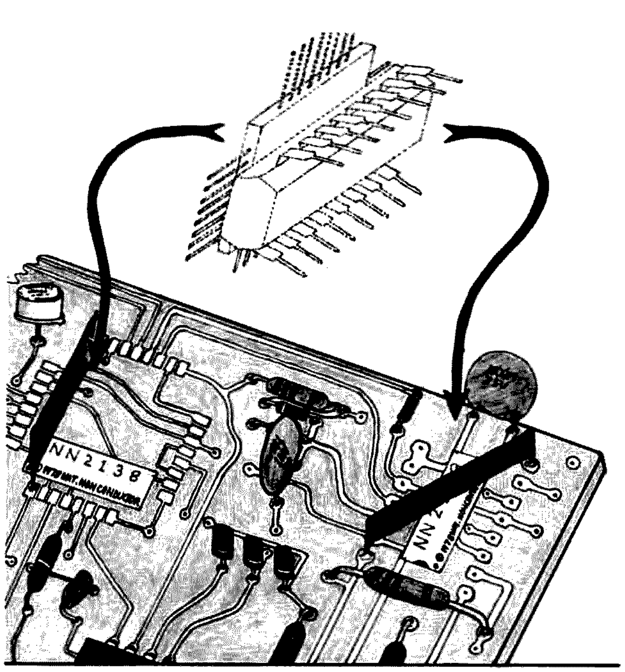

Fig. 6. Vanished "flop-flip" case WOM. Case design would be unwieldy if chip existed.

posal of spent data, rather than simply spraying it into the environment as noise. Future generations of computers will very likely be planet-sized, if not larger, and we are presented with the horrifying spectre of civilizations fighting over caches of transition-free space. Of course, this does not even take into consideration the cost of transporting it to work sites once it is staked out.

In the early days of computer technology, a programmer was as often as not a jumper jockey, wiring by hand the controller boards used to program line printers and the like. The distinction between program and data was painfully clear. This separation is referred to as Harvard Architecture. Those who toiled at these tasks may at least console themselves that the knowledge so gained has been of great benefit in present-day technology. Many MSI integrated circuits are in reality not logic circuits at all; like the controller boards, they are Read-Only Memories. The chip engineer's job in many cases is reduced from tedious design-from-scratch to literally writing functions onto standardized ROM formats.

With flop-based ICs, this is destined to become an even greater boon. Since flop outputs do not follow their inputs, many functions to be written into WOMs can be deleted without any functional impairment. This has been dubbed Dropout Architecture.

It is not difficult to prove that, using Dropout Architecture and conventional ROM table-folding techniques, WOMs can be progressively simplified to the point that they will vanish, making them extremely compact and versatile. Of course, *There Ain't No Such Thing As A Free Lunch*, as they say in the vernacular. In most cases, the IC's supply bypass resistors will not share in these logic-derived benefits. Hefty power supplies will thus remain the rule, given the degree of supply bypassing previously mentioned. Also, good design practice will still call for at least a label to indicate the choice of WOM not to be used. Fig. 6 shows a vanished WOM as it may appear and demonstrates an unusual benefit of the concept. Proposed case outline MO-223 is a "flop-flip" case which can be not used in either a dual-inline or quad-inline circuit board location.

Monodes entered the linear realm in 1972 with the invention of the Zero-Current Source. It is realized in chip form as two powerless monodes in a totem-pole arrangement, providing a 100% offset with respect to both supply and ground simultaneously.

This makes possible the infinite-output-impedance NOP-amp, which is ideally suited for unity gain applications since the output impedance matches the input impedance. As long as no disturbing input signal is present, distortion is extremely low.

Other unique devices are exemplified in designs now on the drawing board at Nationable Nonconductor, a Bull Laboratories subsidiary. For example, the NN3160 and NN3161 are, respectively, a suppressed-leading-zero-to-analog converter and its trailing-zero sister. The NN31246 is an Indefinitely Long Delay Line or "Collander Brigade." It is actually a 1xN analog shift WOM, of course. It is used to shunt signal quiescent periods away from sensing circuit inputs.

A German research group has recently achieved a combination theory/practice coup with the development of the G999. This Gottdeschaft device is a triple negator and is used to cast out nines in decimal arithmetic units.

We can expect the monode to flood the marketplace soon, one-upping many current two-lead devices. With the prospect in sight of a complete engineering revolution, as Dropout Architecture's characteristic philosophy of material economy is applied to many other disciplines, physical technology itself will become a thing to be avoided. We will be ushered into a new Eden and rejoice in Eternal Oneness. ■

Breaking the Decibel Logjam

—how to cope with nothingness

The purpose of this article is to clarify what a decibel is and to explain why it acts the way it does. The average amateur seems to encounter difficulty when studying the subject. It is sometimes difficult to grasp the decibel because of its "nothingness." It has no weight, it cannot be seen, and its taste and smell are nonexistent.

Before going any further, it might be well to state that the decibel is a *ratio*, nothing more and nothing less. It merely represents the relationship between two quantities of energy. Unlike the meter, the pound, or the quart, it has no counterpart in wood or metal in the Bureau of Standards. It is an arbitrary standard originally set up by telephone engineers for their convenience in making measurements and calculations.

The decibel is similar to the old "transmission unit" used for measuring the efficiency of telephone circuits. The original unit was equal to the loss in a mile of standard telephone cable. This mile of cable was used to compare the losses or gains in a circuit.

The mile of standard cable was too bulky to keep around so it was replaced by its electrical equivalent: an artificial line with a resistance of 88 Ohms and a capacitance of 0.054 uF. For measuring purposes, the combination of these units was equal to a mile of standard cable. If the input to a circuit was increased, the amount of increase could be measured by the number of mile-units which had to be inserted to bring the output back to the original level.

The greatest defect of the mile of cable is that the cable, having a certain amount of inductance and capacitance, does not have a flat frequency response, and transmission efficiency depends upon frequency as well as power. In working with new types of circuits, there was a great need for a new unit of transmission which was *independent of frequency*. One was needed which was based on power alone, since the gain or loss in power is the true index of efficiency.

Another measurement scale was devised and the basic unit of transmission, by agreement among the engineers, was the *bel*. It was given this name in honor of Alexander Graham Bell, the inventor of the telephone. In common practice, one tenth of this fundamental unit is used; it is called the decibel and goes by the abbreviation dB.

The decibel is a natural unit based on the way our ears respond to various sound levels. We rate the efficiency and power output of apparatus in Watts, but our ears do not respond to sound energy the same way a meter does. Instead of responding in direct proportion to the wattage, our ears respond *logarithmically* with respect to the power.

For those who may have become a bit doubtful about their algebra, a little review may be in order before continuing with the discussion.

Use of Logarithms

The common system of logarithms uses ten as a base. The logarithm of a number is the power to which ten, the base, must be raised to equal the number. For example, ten squared, or ten raised to the second power (10^2), equals 100. Thus, the logarithm of 100 is 2. If we raise ten to the third power, we have 1000 ($10^3 = 1000$); so the logarithm of 1000 is 3.

The number which we have just found is called the characteristic of the logarithm and always has a value of one less than the number of digits in the given number. 1000 has four digits and so the characteristic of its logarithm is 3. Unless

the given number is a direct power of 10, its logarithm consists of the characteristic followed by a decimal number known as a *mantissa*, which must be found by use of a table of logarithms. If we want to find the logarithm of 775, we know that the characteristic is one less than the number of digits so that makes it 2. By referring to a log table we find the mantissa to be .8893 so the log of 775 is 2.8893. This means that if 10 were raised to the 2.8893 power, the result would be 775. Numbers may be multiplied by adding their logarithms or they may be divided by subtracting their logarithms.

Returning to the discussion of the decibel, suppose we had an amplifier with an even 1000 milliwatts output. If the output were reduced the least amount detectable by a sensitive ear, we would find that it had been reduced to about 794 milliwatts, or to 0.794 of the original power. If once again the power were reduced the slightest amount detectable by the ear (a *good* ear) and the output measured again, we would find that the power had been reduced to 0.794 of the 794 milliwatts, or to 0.630 of the original power. If we go so far as to reduce power another step, we find that the power has been reduced to 500 milliwatts, or to one-half of the original amount. It took three steps (reductions of power) to reduce the original power to one-half its value.

The decibel, which is the new unit of transmission or power ratio, is supposed to be the smallest change in power that is audible to the trained ear. The formula for finding the decibel of a ratio between two power levels is: $dB = 10 \log_{10} (power_1/power_2)$.

Power 1 and power 2 represent power before and after it has been reduced or increased. When substituting, if the larger of the two is always placed on top, it will simplify solution. If we substitute 1000 milliwatts for p_1 and 794 milliwatts for p_2, we will have the following:

$$dB = 10 \log_{10} 1000/794 = 10 \log_{10} 1.259.$$

The log of 1.259 is 0.100, so $dB = 10 \times 0.1$, or, $dB = 1$.

In substituting for the second and third reductions, we find that we have reductions of 2 and 3 dB, respectively. This then gives us an approximate scale that is easy to remember: One dB reduces the power to 4/5ths of the original, two dB reduces it to 2/3rds of the original, and a reduction of three dB brings the power down to one-half of the original.

Practical Examples

If these power ratios are memorized, almost any dB loss or gain can be figured quickly. For example, what power ratio would be represented by a loss of 9 dB? A 9-dB loss would be the same as three 3-dB losses. Remembering that a 3-dB loss equals a power ratio of 1/2 and also remembering that when the logarithms of a number are added the numbers are multiplied, we find the following:

$$3\text{ dB} + 3\text{ dB} + 3\text{ dB} = 1/2 \times 1/2 \times 1/2 = 9\text{ dB} = \text{power ratio of } 1/8.$$

To find the power ratio of a 7-dB loss we have the same as a 3-dB, 3-dB, and 1-dB loss, so:

$$3\text{ dB} + 3\text{ dB} + 1\text{ dB} = 1/2 \times 1/2 \times 4/5 = 7\text{ dB} = \text{power ratio of } 1/5.$$

When solving for gain, the problem is figured for an equivalent loss and the resulting power ratio is inverted. For example, to find the power ratio of a gain of ten dB, we have to find a change of 3 dB, 3 dB, 3 dB, and 1 dB, so it follows that

$$3\text{ dB} + 3\text{ dB} + 3\text{ dB} + 1\text{ dB} = 1/2 \times 1/2 \times 1/2 \times 4/5 = 10\text{ dB} = 1/10.$$

Inverting: 10 dB gain = power ratio of 10.

This is another common ratio that should be committed to memory, and it is easy to remember: 10 dB equals a power ratio of 10.

Voltage or Current Ratios

The formula so far has been for finding the decibel direct from the power measurements. When voltage or current readings are to be used in place of power, the formula must be changed to read:

$$dB = 20 \log_{10} (V_1/V_2).$$

The power in a circuit is proportional to the square of the voltage or current. As stated before, adding of the logarithm of a number to that of another multiplies the numbers, so two times the logarithm of the voltage or current ratio squares it and gives us the power ratio. Current values may be substituted for V_1 and V_2. When using voltage or current values in the formula it is considered that the *input and output impedances are the same*.

By substituting in the formula for power, we can work out the following table.

Decibels Gain	Power Ratio
0	1
1	1.25
10	10
20	100
30	1000
40	10000

By this we find that each time the level in decibels is increased by ten, the power is multiplied by ten. To increase the audio output of a piece of equipment by 40 audible steps, or by 40 dB, the power output must be increased 10,000 times. ■

HAM HELP

I recently purchased an old Hallicrafters linear amplifier, Model HT 41. I need to get a copy of the schematics and, if possible, operating instructions. If anyone can furnish these, I will gladly pay costs. Thank you.

Glenn Churchill KA2IOI

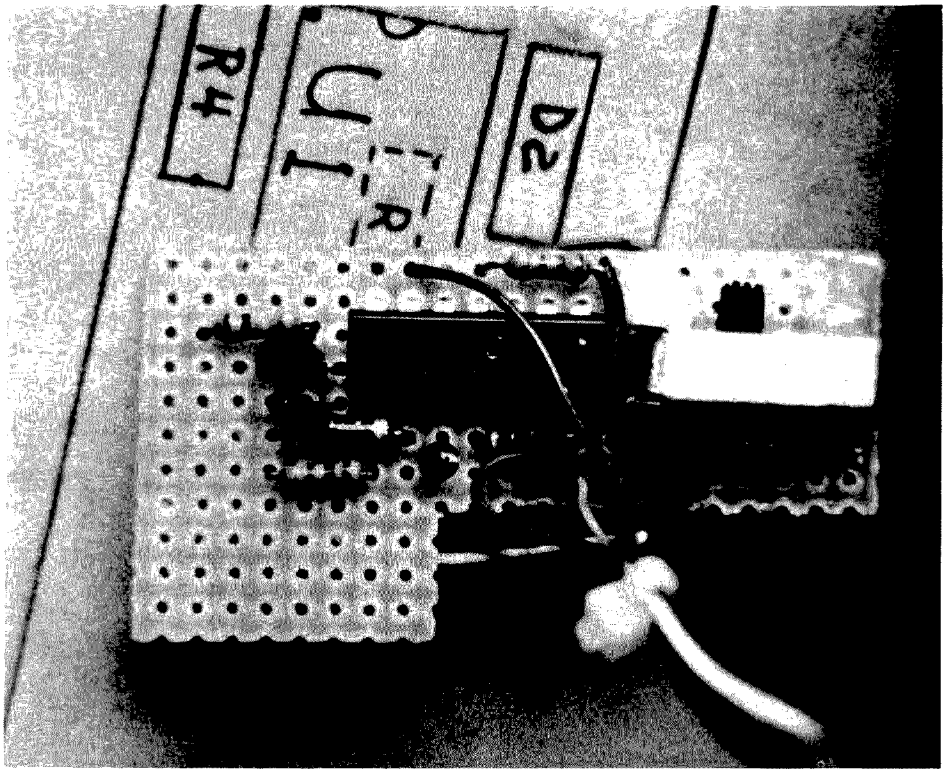
Wilson Mark II and Mark IV hand-helds are excellent performers. In many ways, they rival the premier Motorola HT-220s. One way in which the Wilson units come up short is on standby current. Wilson specifies the standby current at 15 mA; mine draws about 22 mA normally. A call to the factory confirmed that this is par. While respectable, 22 mA, or 15 mA for that matter, just doesn't compare to the HT-220's standby current of 3.5 mA. Recently, while making a modification suggested by Wilson to reduce distortion in the audio stages, I decided to do

something about this. The result was a reduction of the standby current to the outstanding level of 4 mA. Perhaps even more incredible, the modification requires only about $2 worth of parts and just a slight wiring change to the circuit board! The details of the modification are described below, along with two other changes which conserve power on receive and transmit.

The basic idea behind the modification is to switch off the power to most of the receiver as much of the time as possible, switching it on periodically for a brief instant to check for a received signal. When the receiver is powered up, the presence of a quieted signal keeps it on and the absence of a signal turns it off again. Once turned off, the receiver is powered up again after a delay and the process repeats. If the turn-off occurs quickly compared to the time between successive turn-ons, substantial power savings result.

To implement this idea, logically it would seem that checking the squelch voltage of the receiver would be sufficient to determine if a signal is present. In fact, this is the scheme that most scanners use to check for busy channels. However, to prevent noise bursts from coming through, squelch circuits open only after the presence of a continuous quieted signal for some fixed time period. Wilson set this time period to be from 40 to 120 ms, depending on the squelch control setting. The squelch action of the Wilson HT is depicted in Fig. 1, which shows the voltage at the collector of Q14 for various signal conditions. If the squelch control is set as tight as possible, the receiver would have to be powered for 120 ms before the squelch voltage would indicate the presence of a signal. Thus the minimum power-on time would be about 120 ms.



Top view of completed board.

To realize significant power savings, the receiver must be off for much longer periods than it is on. If the receiver power-on period is set to 120 ms, the power-off period must be set to 1 second or longer. This is not acceptable, since it results, on average, in the loss of the first 500 ms of any transmission. If the power-on period could be shortened, however, the power-off period could also be shortened, and hence the amount of any transmission that is missed would be reduced. A power-on period of 10 ms followed by a power-off period of 200 ms, for example, would result in the loss of only 100 ms of signal on average, while still reducing power consumption considerably. A loss of 100 ms corresponds to about one-half of a syllable and is not significant. In fact, this is comparable to the amount of signal lost in normal operation due to the response time of the squelch circuit (see Fig. 1 and note the time delay from signal onset to squelch opening).

Thus, to design a successful power-saving circuit, a method of reducing the required power-on time must be found. Although the squelch circuit of the receiver takes up to 120 ms to open, it closes in at most 15 ms (the squelch circuit closes in about 5 ms if the squelch control is set as tight as possible). Therefore, if instead of waiting for the squelch to open when the receiver is powered, we instead somehow start with the squelch open and only wait for it to close, the power-on periods could be reduced to 15 ms or less. This coupled with power-off periods of 200 ms would yield fairly fast response and dramatic power savings. Unfortunately, the Wilson's squelch circuit always closes after the receiver is powered. However, if the squelch circuit itself is always powered during receive and the rest of the receiver is powered up at intervals of more than 120 ms (the maximum time it takes for the squelch to open), then the squelch would

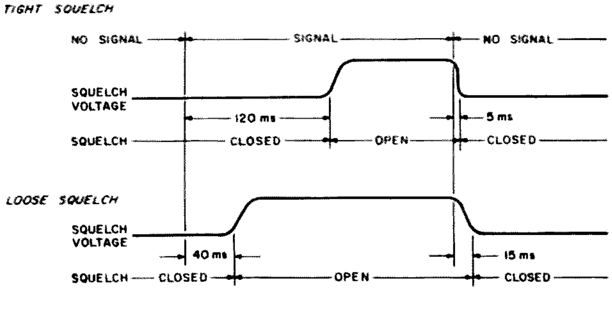


Fig. 1. Squelch action before modification.

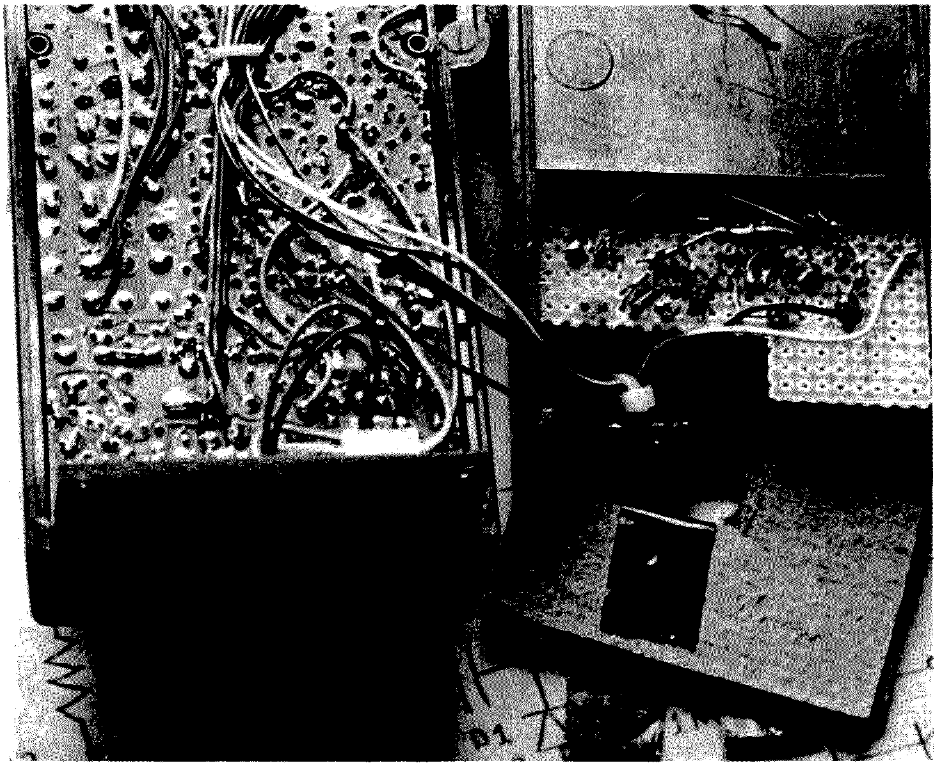

Bottom view of completed board showing method of installation in HT.

always be open at the instant that the receiver is powered. The operation of such a system is shown in Fig. 2.

Although the system now seems complete, another problem has been introduced. Since the audio stages are turned on and draw power whenever the squelch is open, some additional method must be used to keep the audio stages turned off during the time when the squelch is open and the receiver is not powered. This problem turns out to be easily overcome by allowing the receiver power control signal to act as an auxiliary squelch control signal. In this way, the squelch control signal is kept closed when the receiver is not powered. When the receiver is powered, normal squelch action controls the audio stages.

A block diagram of the circuit is shown in Fig. 3.

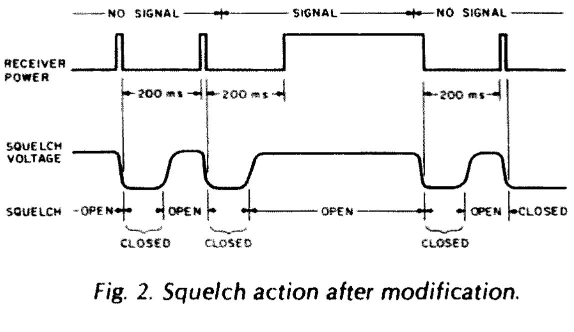

Fig. 2. Squelch action after modification.

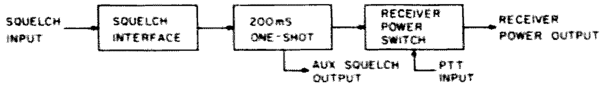

Fig. 3. System block diagram.

The squelch interface converts the squelch signal to logic levels and to some extent duplicates the squelch control stage of the HT. This is necessary because the solution to the problem mentioned above keeps the receiver squelch control stage clamped while the receiver is not powered. The squelch interface circuit triggers the one-shot when the squelch closes. The one-shot sets the length of the power-off period. It also is used to keep the audio stages off during power-off periods via the auxiliary squelch output. When the one-shot is inactive and the HT is in receive mode (PTT is high), the receiver power switch is closed and B+ is applied to the receiver. When the one-shot fires or when the HT goes into transmit mode (PTT is low), the power switch opens and the receiver is turned off.

The complete circuit is shown in Fig. 4. Transistor Q1 converts the squelch voltage to 0 - 12 volts. The one-shot is made from two Schmitt-trigger NAND gates, U1A and U1B. These gates are very useful for fashioning one-shots and oscillators, and the spare gate can be used in some future project. When the output of U1B is low, it shuts off the audio stages through diode D2. U1C controls the receiver power via transistor Q2. The power pulsing action can be disabled by closing switch S1. This keeps Q1 off, preventing the one-shot from firing.

The entire circuit easily fits into the area reserved for a tone encoder. Construction is quick using a perfboard, and a suggested parts layout is shown in Fig. 5. I soldered the IC directly into the circuit, although the board might still fit if a molex™ or a low-profile socket is used. Both unused gate inputs on U1 (pins 1 and 2) must be tied high or grounded. I used 1/4-Watt resistors and tantalum capacitors because of their small size. All parts are readily available from many suppliers. One supplier is Digi-Key, PO Box 677, Thief River Falls MN 56701.

The wiring is as follows: Disconnect the wire from the emitter of Q29 (upper right of the circuit board) to the junction of R5, R6, R9, R11, R13, R14, and C46 (middle of the circuit board). Connect +V on the new board to the collector of Q29. Connect the collector of Q2 on the new board to the junction of the components listed above. Connect the PTT input on the new board to the emitter of Q29. Connect the squelch input on the new board to the collector of Q13 (near the top of the circuit board). Connect the auxiliary squelch output of the new board to the collector of Q14 (upper left of the circuit board). Finally, connect the ground on the new board to the circuit board

ground somewhere near Q14 (the exact location is not critical).

If the disable function is desired, a small slide switch can be mounted on the perfboard. The switch should be bonded to the board (epoxy works fine). By cutting a notch in the case within the battery compartment, the switch can be conveniently reached without disassembling the case.

Circuit operation can be checked by observing the one-shot output (pin 11 on U1) on an oscilloscope. With the HT turned on and the squelch control fully clockwise, a pulse train should be observed. The pulse should be high for about 5 ms and low for about 200 ms. Next, rotate the squelch control to its fully counterclockwise position. The one-shot output should stay high and the receiver squelch should open.

If all is well, install the perfboard in the HT. The board may be glued in place if desired, although I have not found this to be necessary. Insulate the perfboard from the circuit board using cardboard, foam, etc.

The completed unit draws around 3.5 mA during power-off periods and normal receiver current (22 mA in my case) during power-on periods. With the squelch control pegged, the duty cycle is 5 percent or so, and as a result the average current should be approximately 4.5 mA. Measurement in the lab confirmed this figure. The HT was also tested on a Cushman, and no change in receiver sensitivity was observed when switching between pulse mode and normal mode.

Once installed, the operation of the circuit can be verified by rotating the squelch control until the squelch threshold is just reached. Periodic noise pulses should be heard from the speaker if the squelch control is set right on the edge between open and closed. Otherwise, you'll never know it's working unless you keep track of how often your batteries run down!

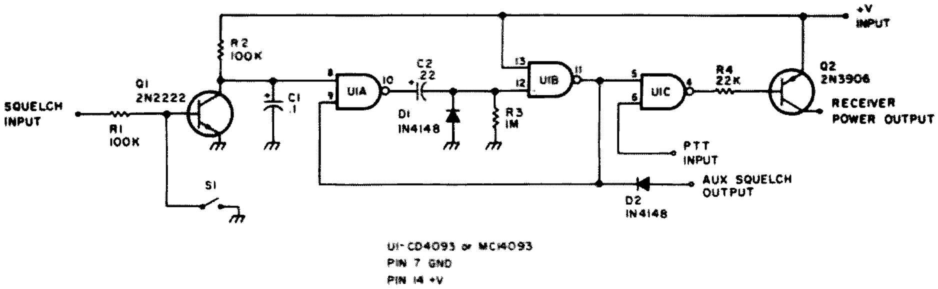

Fig. 4. Power pulser schematic.

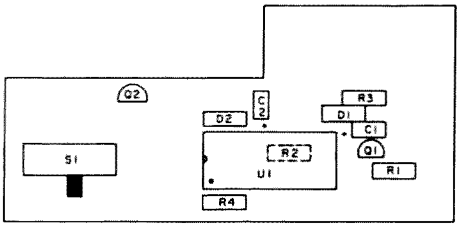

Fig. 5. Parts layout, top view.

Now on to some changes on the circuit board. These changes are not that easy and are only recommended for those persons experienced with tight circuit-board work. Although the changes only involve substitution of components, access is difficult due to the cramped quarters. With a little care they may be performed successfully.

The first change further reduces receiver standby current drain, although only by a little more than .5 mA (from 4.5 to 4 mA). Change R48 from 18k to 100k. R50 should now be adjusted so that the audio output clips symmetrically. A value of 270k worked for me. A side effect of this modification is that the time it takes the squelch to open is increased by about 20 ms. C57 could be reduced to compensate for this, but then the squelch would close on shorter noise pulses than it did originally. I suggest leaving C57 at 1 uF, since the added time is not significant. Although this modification can be made without installing the power pulsing circuitry, the benefit would be marginal in that case.

The second change reduces transmit current by about 20 mA. Change R93 from 470 to 4.7k. This change cannot be made unless the power pulsing circuitry has been installed. A similar savings in transmit current can be achieved without installing the power pulser, however, at the cost of about .7 V lower receiver voltage, by changing Q29 to a Darlington (such as an MPS A13) and increasing R93 to 10k.

In conclusion, I see no reason why the receiver power pulsing idea could not be adapted to other HTs. For synthesized HTs, power would have to be maintained to the synthesizer, since the lock-up times are probably on the order of 100 ms. Give it a try!

Finally, I'd like to acknowledge the help of N3IC in kicking ideas around, designing circuits, and taking the photos, and also thank N3TE for sparking the whole process. ■

A Positive Supply with a Negative Chip

—one way to solve the parts problem

From time to time you, like myself, have gotten into a situation where your junk box just did not have the right parts needed to build a project. You found yourself needing some critical components not immediately available from the parts store—or maybe it's 9:00 pm, Sunday night.

Well, this is a story about such a situation which I wish to share with you.

One evening, while working on a new ATV transmitter, I had a requirement for a good regulated power supply. A look into my junk box revealed a shortage of positive-reference regulators.

Again, one of Edsel Murphy's laws prevailed: "If working on a new design, the most critical part will be missing." (Well, if that isn't one of Murphy's laws, it sure is one of mine.) Staring into the junk box, I recognized some LM-337 regulators. This regulator is a negative-reference voltage device, but did this matter?

I walked over to the blackboard and quickly drew a schematic of a negative-regulated supply (Fig. 1). It became obvious that there was no reason not to use it. I located the other components needed for this power supply—which I was planning to make adjustable to 13.5 volts—and laid out a breadboard.

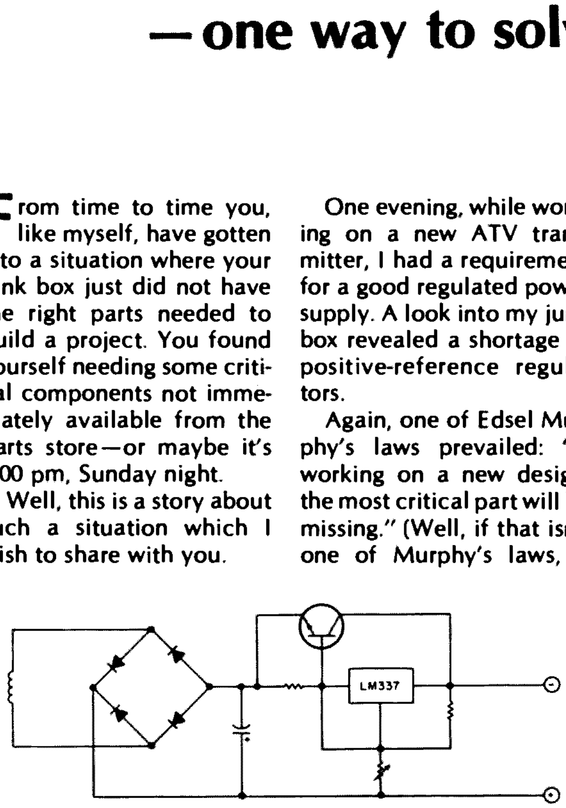

Fig. 1.

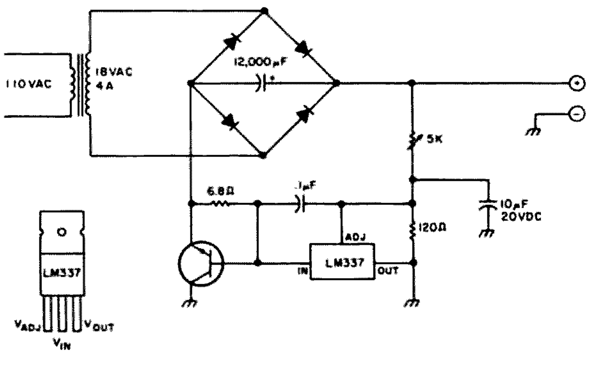

Fig. 2.

While working on the breadboard, certain benefits of this type of design suddenly became evident. Notice in the schematic that I have utilized collector feedback for good regulation. (Of course, this required a more available NPN transistor, as least as far as my junk box is concerned.) Now that is the first plus. The second plus in this design is the fact that we can ground to the chassis the collector of the pass transistor (Fig. 2). Plus number three: using a TO-3 package allowed me to eliminate any need for isolating the case of the pass transistor as is required by every other supply.

Wouldn't you think, with all these pluses, that although this supply uses a negative regulator it should come out plus? Hi!

In previous designs (see "More Power to You," *73*, August, 1979), I discussed details of regulated supplies, current limit, regulators, crowbar circuits, etc. I wish to keep this design simple and very basic. With that in mind, let's examine it briefly.

The transformer is an 18-V, 4-Amp unit purchased at Radio Shack (PN 273-1514). Referring to Fig. 3, we can see the calculations to the rectifier assembly. This rectifier bridge is from Radio Shack (PN 276-1171) and has a rating of 100 piv at 4 Amps.

A good rule of thumb for the filter capacitor is approximately 3000 uF per Amp. With this 4-Amp supply, I paralleled four 3300-uF units from my junk box.

Referring to Fig. 4, we can calculate the dissipation of the pass transistor to determine the proper heat-sink rating. Starting with a dc level of 25 volts from the unregulated supply and a regulated output of 13.5 V,

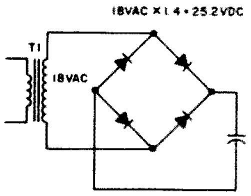

Fig. 3. Full-wave bridge, filtered and unregulated.

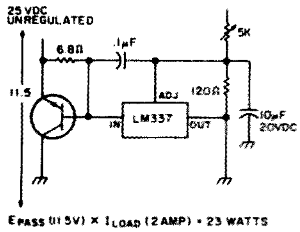

Fig. 4.

the difference voltage across the pass transistor will be 11.5 V. The product of the difference voltage and the load current will be the power dissipation, in Watts, by the power transistor. For example, 11.5 V × 2 Amps (load current) equals 23 Watts of heat in the transistor. With this in mind, I would recommend a 100-Watt power transistor like Radio Shack's PN 276-2039. A companion heat sink could be the Radio Shack Universal (PN 276-1361).

The remaining parts are not magic. Any ½-Watt resistor can be used for the regulator bias. Due to the fact that the supply was designed for 4 Amps, the LM-337 requires a heat sink to handle about 3 Watts (Radio Shack PN 276-1363).

The only cautions to be exercised to keep the 3-lead regulator stable are lead length, wire routing, and grounding. Ground loops and stray current paths can cause stability problems resulting in the regulator not functioning under load, so lay out your package carefully.

Edsel Murphy may have the corner on the unusual-situation market, but I have the first on a negative coming out positive! ■

FUN!

John Edwards KI2U
78-56 86th Street
Glendale NY 11385

As the year draws to a close, our thoughts return home. The holiday season arrives, and one longs to be with family.

Well, it may not be family in the traditional sense, but "home" for the FUN! column is *73 Magazine*. This month, we take an affectionate look at the old homestead and contemplate, with some curiosity, what our hobby would be like without it.

ELEMENT 1—CROSSWORD PUZZLE (Illustration 1)

Across

ELEMENT 2—MULTIPLE CHOICE

1) During this publication's early days, Wayne Green would often extol the virtues of his favorite car. It was:
   1. a 1912 Buick
   2. a Porsche
   3. a Volvo
   4. a Fiat

2) When this column first appeared, in October, 1980, it was written by WB2IBE. Whatever happened to him?
   1. He quit to write a similar column for *Creative Computing*
   2. He died
   3. He retired
   4. He upgraded and changed his call to KI2U

3) What was *73*'s original cover price?
   1. 37¢
   2. 73¢
   3. 75¢
   4. 88¢

4) How much did a life subscription cost in December, 1961?
   1. $30
   2. $50
   3. $75
   4. $100

5) Which person listed below has *not* been a DX columnist for *73*?
   1. James Cain K1TN
   2. Floyd Vivino WA2DCS
   3. Chuck Stuart N5KC
   4. Yuri Blanarovich VE3BMV

ELEMENT 3—TRUE-FALSE

	True	False
1) During this magazine's first two years, it was printed on green paper to differentiate it from the competition.	____	____

Illustration 2.

2) From 1965 to 1971, the *Cigar Smoker's Journal* was a *73* publication. ______ ______
3) Wayne Green once edited *CQ Magazine*. ______ ______
4) The ARRL had a full-page ad in *73*'s first issue. ______ ______
5) A *73* FUN! editor once campaigned for ARRL office by handing out promotional rolling paper. ______ ______
6) *73* is available in microfilm from University Microfilm, Ann Arbor, Michigan. ______ ______
7) While this year's "FUN! Poll" counted 612 ballots, the actual response was closer to 1,000. ______ ______
8) "RTTY Loop" made its *73* debut in the June, 1977, issue. ______ ______
9) The first item ever described in *73*'s "New Products" section was an Allied catalog. ______ ______
10) Wayne Green, in addition to his many other responsibilities, is also the mayor of Peterborough, New Hampshire. ______ ______
11) YA1NSD was Wayne's callsign in Afghanistan. ______ ______
12) *73* also publishes *HR Report*. ______ ______
13) The ARRL subscribes to *73*. ______ ______
14) Mickey Mouse once appeared on *73*'s cover. ______ ______
15) In 1976, *73* published 13 issues. ______ ______
16) Someone once wrote to "Ham Help" asking for assistance in building a particle beam. ______ ______
17) A 1980 *73* profile of Dick Bash opened with the quote, "Morality? Man, who am I to judge morality?" ______ ______
18) Before this *73*, there were others. ______ ______
19) "*73* ON-THE-AIR" is the name of *73*'s monthly cable TV program. ______ ______
20) A *73* columnist was once interviewed by Johnny Carson on the "Tonight Show." ______ ______

ELEMENT 4—FILL IN THE BLANKS

1) You are reading issue #____ (no peeking).
2) Along with "Never Say Die," the other three original *73* features still being run are __________, __________, and __________.
3) "Well . . . I Can _______, Can't I?"
4) "ARRL: Love it, Hate it, _____ _____."
5) As editor of *Astounding Science Fiction*, he gave sci fi writers such as Isaac Asimov and Robert Heinlein their first national exposure. Later, he wrote an article for the first issue of *73* and was listed as a contributing editor. His name was _____ _______.

ELEMENT 5—HIDDEN WORDS
(Illustration 2)

Hidden in this puzzle are the name of ten past and present *73* features. The words are formed in any direction—horizontally, vertically, or diagonally, forwards or backwards. As you find each word, circle it.

THE ANSWERS

Element 1:
See Illustration 1A.

Element 2:
1)—2. Fun, if you can afford it.
2)—4. A truly remarkable fellow.
3)—1. Imagine a time when 73¢ was too much to charge for a magazine!
4)—1. Wayne told you it was a great deal.
5)—2. But he's available.

Element 3:

1)—False	Come on!
2)—False	Hardly.
3)—True	And it hasn't been the same publication since.
4)—False	Would you believe a classified?
5)—True	It seemed like a good idea at the time—but I lost.
6)—True	Yeah, but I have to squint to read it.
7)—True	Next time, I'll wait longer before counting.
8)—True	And it's still going strong.
9)—True	To the delight of amateurs everywhere.
10)—False	At least I think not.
11)—True	Not recently.
12)—False	Right state, wrong company.
13)—True	Of course. My *73* issue #1, by the way, is stamped: "Received: ARRL HQ." I got it this year at a local flea market. A real collector's item, no?
14)—True	September, 1977, being printed on a Teletype.
15)—True	The usual 12, plus a special year-end "Holiday" issue.
16)—False	If this one were true, OSCAR might be in trouble.

17)—True Morality? Man, I just take the cash and run.
18)—True As you may have guessed, *73* was a popular title for various club newsletters and other ham publications. The 1960 *73* stuck.
19)—False *73*'s Tuesday night skeds.
20)—True Johnny and I chatted back in 1969.

Element 4:
1)—255; 2)—Propagation, Letters, New Products; 3)—Dream; 4)—Don't care; 5)—John Campbell.

Element 5:
See Illustration 2A.

SCORING

Element 1:
Twenty points for the completed puzzle, or 1/2 point for each question correctly answered.

Element 2:
Four points for each correct answer.

Element 3:
One point for each correct answer.

Element 4:
Four points for each blank filled.

Element 5:
Two points for each word found.

Think you know this magazine?

1-20 points "*73 Magazine*? Oh, is that what I'm reading?"
21-40 points Once wrote a letter to Wayne complaining about a misleading question in the FUN! column.
41-60 points Bums issues off of friends.
61-80 points is an ardent subscriber.
81-100+ points Has memorized the yearly indices.

AWARDS

Bill Gosney KE7C
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

KOREAN AMATEUR RADIO LEAGUE AWARDS

This week I was the happy recipient of a very nice letter from the Korean Amateur Radio League. Two very attractive awards were among the material received and it's my honor to share the KARL AWARDS with you now.

AKA, the Worked All Korean Prefix Award, is issued to amateurs and shortwave listening stations worldwide on payment of a fee of 5 IRCs and an award application.

Each claim must be accompanied by a list of Korean prefixes worked in prefix order. Each list must be accompanied by a signed verification of two amateurs that the applicant has confirmation of each contact in his or her possession at the time of application. Please *do not* send QSL cards; the verified list will suffice.

Cards dated on or after January 1, 1959, will qualify. Contacts made from any location within your call area are eligible. Contacts with HL9 stations will be graciously accepted.

All correspondence should be sent to Awards Manager, Korean Amateur Radio League, CPO Box 162, Seoul Central, Korea.

The HM Award, formerly known as HMA, has identical application requirements, with the exception that the award is issued for total HM/HL QSOs worked in any one of five Award Classes. The following classes apply: Class K, O, R, E, and A. Spelling out the country's name, the classes require 5, 10, 20, 30, and 50 QSOs respectively to qualify.

When applying for either of these classic Asian awards, tell our friends in the "land of morning calm" that you read about it in *73 Magazine!*

BULGARIAN 1300 AWARD

The Bulgarian Federation of Radio Amateurs introduces the award, Bulgaria—1300, to commemorate the 1300th anniversary of the foundation of the Bulgarian State, in 681 AD.

This award will be issued to licensed radio amateurs throughout the world having the necessary score for established two-way radio contacts with Bulgarian amateurs. To be eligible, all contacts must be made in the period January 1, 1980, through December 31, 1981. This gives our readers only a month, so you'd better hurry and work a few contests before the deadline!

The award is available in three categories: Class 1—requires 1300 QSO points; Class 2—requires 1000 QSO points; Class 3—requires 500 QSO points.

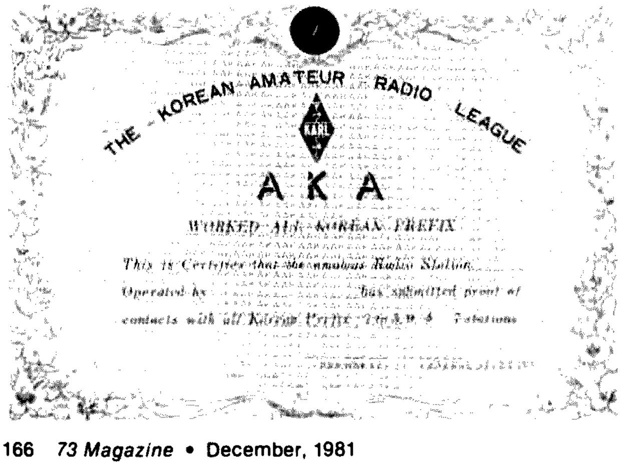
QSO points are earned as follows: 30 points for QSOs with any Bulgarian amateur located in the capitals of Bulgaria working with the prefixes LZ13. These are LZ13C (Sofia, The Central Radio Club); LZ13CSF (Sofia); LZ13CPL (Pliska); LZ13CPR (Preslav), and LZ13CWT (Veliko Tirnovo). Five (5) QSO points are earned for contact with any other LZ station irrespective of his or her callsign.

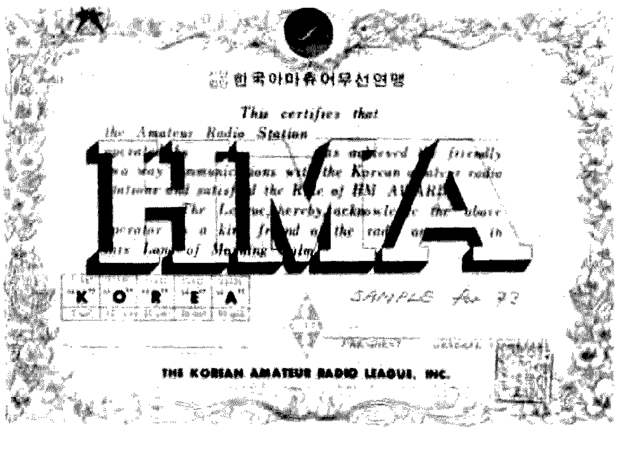
Regardless of operating mode, contacts may be made once per hand. The award is issued free of charge and the only requirements of major concern are that your contacts should be listed in prefix order, and the list be verified by at least two fellow amateurs.

Applicants may apply for this award any time up to December 31, 1982. Remember, however, that all contacts must be made *before December 31, 1981*, to be valid. Send your application to: P.R. of Bulgaria, Sofia 1000, PO Box 830, Bulgaria.

WORKED LA3FL/MM AWARD

The three radio officers aboard the *Royal Viking Sea*, a Norwegian ship which cruises





LA3FL/MM

all over the world, are offering free the Worked LA3FL/MM Award.

Applicants *must* work the station on CW in four different bands, minimum of 539 RST. A QSL card must be sent for each band to the LA bureau or to Per A. Mikalsen, Chief Radio Officer, *Royal Viking Sea*, Ruseløkkveien 14, Oslo, Norway.

CHIEF R/O

M/S ROYAL VIKING SEA

FESSENDEN'S 75TH

During the week of Christmas, 1981, AA1A will be operating most HF SSB phone bands to commemorate the 75th anniversary of the experiments by Reginald Fessenden, who made two-way contacts with Scotland as well as the famous Christmas Eve voice broadcasts. Fessenden also was responsible for many radio firsts as well as many innovations such as the heterodyne principle and high frequency alternators. He later was the developer of sonar.

Special QSLs will be sent out with more information to those who work us. We will be operating near the lower edge of the General class bands.

Two books are available for those interested in a famous early radio experimenter: *Fessenden, Builder of Tomorrows*, by Helen M. Fessenden, and *Radio's First Voice*, by Ormond Raby.

BETHLEHEM, INDIANA, CHRISTMAS EXPEDITION

The Clark County ARC, Jeffersonville, Indiana, will operate from Bethlehem, Indiana, from 1700 UTC, December 12 to 1700 UTC, December 13. Operating frequencies for W9WWI/9 will be 3.905, 7.240, 14.290, 21.365 MHz on SSB as propagation permits. The N9RM 146.25/.85 repeater will be used for local contacts.

A special 8½" × 11" Christmas season certificate imprinted with the unique Bethlehem postal hand stamps will be sent to all stations who QSL. Please QSL with a large SASE to Clark County ARC, PO Box 532, Jeffersonville IN 47130.

BETHLEHEM, WEST VIRGINIA, EXPEDITIONS

The Triple States Radio Amateur Club will operate from Bethlehem, West Virginia, from December 17 to December 21, from 1400 to 2300 UTC daily. Operating frequencies for WD8DDL/8 will be 7.275, 14.325, 21.425, and 28.550 MHz on SSB, and 7.110, 14.075, 21.110, and 28.110 MHz on CW.

A special holiday-season card will be sent to all contacts. Send an SASE to TSRAC, 26 Maple Lane, Bethlehem, Wheeling WV 26003.

BIG SKY WORKED ALL COUNTIES AWARD

Recently, the Lower Yellowstone Amateur Radio Club of the Sidney/Glendive area of Montana decided to sponsor a Montana Counties Award. The certificate was the idea of WB7UTJ and N7BMR.

To qualify for this award, any licensed amateur must contact and have received a QSL for all 56 counties in Montana on any band or mode of operation. Repeater contacts will not be acceptable, and all QSOs to be valid must have taken place on or after January 1, 1980.

To apply for the award, have your list verified by two other amateurs and send an award fee of one dollar (US funds) and two first-class stamps to either WB7UTJ or N7BMR.

The Kauai Amateur Radio Club is pleased to announce the establishment of five awards which are now available to amateurs worldwide.

WORKED KAUAI AWARD

The WK Award requires all contacts be made January 1, 1980, or later on any band or mode of operation. For applicants in all 50 states and Canada, five KARC member stations must be worked. DX stations need only three contacts with KARC members. General certification rules apply.

WORKED HAWAII AWARD

The WH Award has the same requirements of the WK Award

except that for US and Canadian amateurs 50 Hawaiian contacts must be logged, five of which must be KARC members. For DX stations, 15 Hawaiian stations must be worked and one must be a KARC member.

WORKED HAWAIIAN ISLANDS AWARD

To qualify for the WHI Award, five Hawaiian stations must be worked on the following Hawaiian Islands: Hawaii, Kauai, Maui, and Oahu.

WORKED ALL HAWAIIAN ISLANDS

The WAHI Award requires the applicant to work a minimum of one station on each of the following islands: Hawaii, Kahoolawe, Kauai, Lanai, Molokai, Maui, Niihau, and Oahu.

WORKED ALL HAWAIIAN COUNTIES AWARD

There are a total of five (5) counties in the state of Hawaii. To qualify for the WAHC Award, one Hawaiian station must be worked in the counties of Hawaii, Honolulu, Kalawao, Kauai, and Maui.

Be sure to enclose $1.00 for each award being applied for the help defray costs incurred in maintaining this program series. All correspondence should be directed to the Awards Manager, KARC, PO Box 548, Kalaheo HI 96741.

SANTA CLAUS, INDIANA

The Pike County Amateur Radio Club of Winslow, Indiana, and the Old Post Amateur Radio Society of Vincennes, Indiana, will operate a special events station from Santa Claus, Indiana.

The callsign will be W9CZH, and the dates, December 4, 5, and 6. Starting time is 0000Z on the 4th, continuing on through to 2300Z on the 6th. Frequencies (plus or minus QRM): 21.410, 14.305, 7.270, and 3.925 SSB, 14.090-14.100 RTTY, and 146.52 FM.

A special QSL/Xmas card postmarked from the Santa Claus post office will be sent upon receipt of an SASE. Send to Santa Claus, PO Box 111, Ireland IN 47545.

MOUNT SAINT HELENS AWARD

Down the road a mere 180 miles sits majestic Mount St. Helens. We here in Washington remember the historic Sunday morning very well. Supported in the community by a Naval Air Station, we thought for sure bombing maneuvers were underway here on Whidbey Island. Instead, what we were hearing was the explosion and the awesome eruption of Mount St. Helens, a devastating act of nature which had happened some 14 minutes earlier (took this long for us to hear it at the speed of sound). By this time, radio announcers had already received the unfortunate news over the wire services, and aftershocks were being experienced which were to continue for weeks and months to come.

The amateurs throughout the area performed marvelously in the hours of desperation. It behooves all of us, sometime in our amateur careers, to contact amateurs from the region and listen to the story they have to tell!

A unique photographic award of the Mt. St. Helens eruption on May 18, 1980, is now available. Two opportunities, with no mode or band restrictions, are provided to qualify for this very popular award:

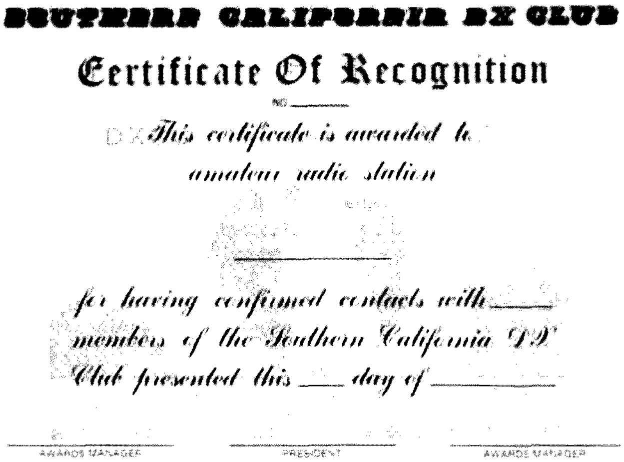
1) Contact 8 or more stations within the counties of Washington that surround Mount St. Helens (Clark, Cowlitz, Skamania, and Lewis counties). All contacts must be made on or after March 27, 1980, which was the actual first eruption of the mountain in over 123 years.

2) Report one contact with W7AIA (Clark County Amateur Radio Club) during its operation from 0200 UTC May 16 to 0200 May 18, 1981. That marked the first anniversary of the disastrous eruption that took the life of Reid Blackburn KA7AMF, who was a member of this sponsoring organization.

To apply for this award, send appropriate log information and $2.00 or more as a donation to the Reid Blackburn Scholarship Fund which has been established in memory of our dedicated friend and fellow amateur. Forward your application to Awards Manager, PO Box 1424, Vancouver WA 98668.

SOUTHERN CALIFORNIA DX CLUB AWARD

This week I received a very nice letter from Norm Friedman W6ORD, representing the Southern California DX Club, Incorporated. In his letter, Norm announced a Certificate of Recognition which is issued to amateurs throughout the world who can qualify.



Each applicant must work and confirm contact with 35 current members of the DX Club on any frequency from 1.8 to 30 MHz. This will qualify the applicant for the basic award. A bronze seal will be issued for 75 contacts, a silver seal for 100 contacts, and a gold seal will be presented for 125 contacts with Southern California DX Club members.

Verification of these contacts can be administered by any ARRL or IARU affiliated club. All contacts must be made on or after January 1, 1980, to be valid.

Send your list of contacts and $2.00 US funds or 10 IRCs to Norm Friedman W6ORD. For a current membership roster of the DX Club members, send an SASE and 2 IRCs to Norm and he will be sure a copy is rushed to your door.

CORRECTIONS

Figure 8 in "Folded Unipole for 160," on page 32 of the October issue, refers to an swr of "0". Such a value is impossible to obtain. The graph should have a low point of 1.0.

Also, the review of Kenwood's TR-9000, beginning on page 30 of the August issue, refers to measuring power over a range of 143.3 to 148.7 MHz. This should read: 143.9 to 148.7 MHz.

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place.

FAIRBAULT MN
DEC 5

The Courage Center Handi-Ham System will hold its annual winter hamfest on Saturday, December 5, 1981, at the Eagles Club, Fairbault MN. There will be a flea market, a dinner at noon, a program, and prizes. For more information, contact Don Franz WØFIT, 1114 Frank Avenue, Albert Lea MN 56007.

HAZEL PARK MI
DEC 6

The 16th annual Hazel Park Amateur Radio Club Swap & Shop will be held on Sunday, December 6, 1981, at Hazel Park High School, Hughes Street at 9½ Mile Road, 1 mile east of I-75, Hazel Park MI. Tickets are $2.00 and tables are 75¢ per foot. Doors will open at 8:00 with the main prize drawing at 2:00 pm. There will be plenty of food and free parking, plus hourly door prizes. Grand prizes are included with the admission ticket. Talk-in on 146.52. For more information, send an SASE to Jack Field W8UPU, 1444 E. Evelyn, Hazel Park MI 48030.

SOUTH BEND IN
JAN 3

A hamfest swap and shop will be held on Sunday, January 3, 1982, at Century Center, downtown on US 33 one way north between the St. Joseph Bank Building and the river, South Bend IN. Tables are $3.00 each. There is a half acre of carpeted room in the same building as the industrial history museum. Talk-in on .52/.52, .99/.39, .93/.33, .78/.18, .69/.09, and 144.83/145.43. For more information, contact Wayne Werts K9IXU, 1889 Riverside Drive, South Bend IN 46616, or phone (219)-233-5307.

WEST ALLIS WI
JAN 9

The West Allis RAC will hold its 10th annual all-indoor Midwinter Swapfest on Saturday, January 9, 1982, beginning at 8:00 am at the Waukesha County Exposition Center. Advance tickets are $2.00 and tickets at the door are $3.00. Reserved 4-foot tables are $3.00, at the door, $2.00, and on the balcony, free. Included with the ticket will

be a 50¢ coupon toward a sandwich purchase. Prizes will be awarded. For more information, write 1982 Swapfest, PO Box 1072, Milwaukee WI 53201.

RICHMOND VA
JAN 10

The Richmond Amateur Telecommunications Society will hold its annual Frostfest on Sunday, January 10, 1982, from 8:00 am to 4:00 pm at the Virginia State Fairgrounds, Richmond VA. Admission is $3.00 plus a table charge for exhibitors and flea-market displays. Overnight trailer parking with complete hookups will be available at $7.00 per night. Various prizes will be given away during the day with three main prizes to be awarded at 3:00 pm. There will be approximately one acre of indoor heated and well-lighted space. Talk-in on 146.34/.94, 146.28/.88, and 146.52. For additional information, call Joe Stern W4LD at (804)-737-0333.

ARLINGTON HEIGHTS IL
FEB 7

The Wheaton Community Radio Amateurs will hold their annual hamfest on February 7, 1982, beginning at 8:00 am at the Arlington Park Race Track EXPO Center, Arlington Heights IL. Tickets are $3.00 at the entrance and $2.50 in advance. There will be free flea-market tables, expanded floor space, parking, awards, and a large commercial area, including the new computer section. Talk-in on 146.01/.61 and 146.94. For commercial info, call WB9TTE at (312)-766-1684; for general info, call WB9PWM at (312)-629-1427. For tickets, send an SASE to WCRA, PO Box QSL, Wheaton IL 60187.

LIVONIA MI
FEB 28

The Livonia Amateur Radio Club will hold its 12th annual LARC Swap 'n Shop on Sunday, February 28, 1982, from 8:00 am to 4:00 pm at Churchill High School, Livonia MI. There will be plenty of tables, door prizes, refreshments, and free parking. Talk-in on 146.52. Reserved table space of 12-foot minimum is available. For further information, send an SASE (4 × 9) to Neil Coffin WA8GWL, c/o Livonia Amateur Radio Club, PO Box 2111, Livonia MI 48151.

DX BULLETIN OF THE MONTH

As we have mentioned in the past, it is extremely helpful to subscribe to one of the bulletins in order to be in touch with what is happening out there in the DX jungle. To show what one of the better DX bulletins looks like, let's take a look at *The DX Bulletin.*

It's a weekly publication edited and published by Jim Cain K1TN, a well-known DXer, contester, and "well-cooked" ham. *TDXB* provides fresh and up-to-date information about DX activity, happenings that relate to DXing and contests, notes on equipment and conventions, records of stuff worked on the bands, QSL information, and notes on propagation. All in all, it's a very well-written publication. The subscription rates are $26 per year for W, VE, and XE (others: $35). The address is 306 Vernon Ave, Vernon CT 06066.

Well, Merry Christmas and Happy New Year! May you work all the new ones you still need!

WELL-COOKED OR INSTANT HAM?

During my summer vacations, thanks to the lousy rainy weather, I had the pleasure to visit a bunch of really nice hams on Long Island (NY). Among other things, I also had an opportunity to lay my hands on a Signal One CX11. What a machine! It's very tempting and makes you feel like mortgaging your house to get one.

The main thing I would like to highlight is the people—true hams—whom I had the pleasure to meet. What is the big deal about this?

What we are witnessing today is an influx of new "instant" hams who are the products of ham colleges which have all kinds of instant miraculous ways to get you legally on the ham bands and talking as soon as you can. Let's have a look at this group. Typically, they are an outgrowth of the CB generation in which, to get on the radio, all you had to do was pay your bucks and get the best (most expensive) radio, big "shoes," and a tower. Typically, too, they got fed up with all the regulations and quickly found that there were more frequencies around than those they were "forced" to be on. So here comes the vfo and 1- or even 10-kW amplifier. They start using their "freedom of speech" all over the bands, including commercial and amateur. They usually talk about nothing—and they can do that for quite a while.

Then comes the discovery that there are hams who can use vfo's and kilowatts legally and that things are more decent on the ham bands. You don't hear so many carriers. They get interested and some of them simply retune their rigs down there, pick a callsign, and you know the rest. Some go and take courses, "suffer" through the "nonsense," and finally manage to get their tickets. You can tell them from the crowd if you listen in the pileups: they usually call for five minutes without stopping.

Our compliments to those CBers who are basically law-abiding, got fed up with the mess around 27 MHz and then got genuinely interested in ham radio. They got their licenses and tried to learn as much as they could. They discovered a whole new world and enjoy learning more about all the aspects of radio communication: equipment, antennas, propagation, etc. They are a welcome contribution to the hobby.

If we look back a few years, when CB wasn't around, the situation was different. You usually started as an SWL or by seeing another ham's station. The process involved not only talking on the bands, but also a great amount of interest and activity in designing, building, and experimenting with equipment.

The DX Bulletin

ISSUE 106 SEPTEMBER 19, 1981

PROPAGATION: Sep 19, Below Normal; Sep 20, Low Normal; Sep 21, High/Low Normal; Sep 22, High/Above Normal; Sep 23, High/Low Normal; Sep 24, High Normal; Sep 25, High/Low Normal; Sep 26, 27, High Normal; Sep 28, High/Above Normal; Sep 29, High/Low Normal; Sep 30, High/Above Normal; Oct 1, High Normal; Oct 2, High/Low Normal; Oct 3, High Normal; Oct 4, 5, Above Normal. TNX N4XX.

A PIN DROPPED...

And you could hear it on 14225 last Saturday (Sep 12), even though it seemed the whole world was listening. "W7PHO, this is K7LAY/BY Shanghai, you're five by nine."

K7LAY/BY was a demonstration station in Shanghai by Bob Hudson and other members of the Boeing radio club; they were set up mainly to work a Chinese station in Bejing, which was signing "CIE." That contact lasted ten minutes, followed by the pre-arranged schedule with W7PHO and two other stations, including a club station in Washington state and a station on a Marianas chain island. It seemed that hundreds of DXers had heard of the planned schedule over the air and awaited the call from Hudson and his loaned TR-7 from Drake.

While some informal authorization for the transmissions had been obtained, it was realized that these contacts would not be counting for anybody's DXCC; that was not the idea. The idea was to make a further breakthrough toward real Chinese amateur operations in the future. Apparently in that respect the operation was a success. The station could be heard all over the U.S.

K1CC in POLAND

Rich Assarabowski, just back from Poland, reports the convention he attended near the SP9KRT club site in southern Poland was a success, with several hundred hams in attendance despite the increasingly desperate situation there. At the same time, the convention of the Solidarity Union was being held at the other end of the country, on the Baltic Sea coast.

Rich made about 2,000 contacts himself as SO3CC, from the home of SP3DOI, and operated a little fm on 2 Meters (simplex only, no SP repeaters yet). Despite mostly homebrew radios and severe TVI problems, among Poland's 7,000 hams (out of some 35 million citizens) amateur radio is alive and well. Rich's slide presentation dispelled a notion common in Europe that U.S. DXers are very loud due to running "big power." After seeing some of the tall towers and multi-element arrays several of the local DXers were heard planning new towers and quad antennas. Poles are also now getting interested in using their new privileges on RTTY and SSTV.

W9DXCC CONVENTION

Convention chairman K9KM reports about 150 attendees last weekend for this long-running event, down about ten percent from previous years. Special mention was made of the presentations by Dick Ehrhorn, W4ETO, of Alpha amplifiers, and by Dana Atchley, W1CF, who spoke on antennas for 80 and 160 Meters.

The DX HOG OF THE YEAR crown was placed on the deserving head of Al De Marre, K9RF, who was also awarded a special trophy dubbed the "Repeater Usage Award." The HOG is a fun award going back to the very beginning of the W9DXCC Convention.

ARRL was represented ably by Ron Search, W3AZD. While the meeting was marred by having only four representatives from Indiana (none from Indianapolis), Milwaukee looks like a growing DX hotspot, with many in attendance from that metropolitan area.

The DX Bulletin (ISSN 0279-8077) is published weekly for $26 per year in the U.S., Canada and Mexico; all others $35 per year. *The DX Bulletin* is published at 306 Vernon Ave., Vernon, CT 06066 Second-class postage paid at Vernon, CT. POSTMASTER: Send address changes to The DX Bulletin, 306 Vernon Ave., Vernon, CT 06066

THE DX BULLETIN SEPTEMBER 19, 1981

OE2WL and OE1MXA have been very active on their Pacific operations, first /KH8 American Samoa, last week as ZK2TA Niue. They were slated to finish up there about Sep 15 and then operate from Tonga A35 or Tokelau ZM7 until the 21st. After that the last legs of the trip will include the Kiribatis and possibly Nauru. Their activity seems to have concentrated on CW and they have been workable easily on both 40 and 80 Meters.

DJ6SI started his African work on schedule from 5V7ML Sep 12 and was expected to appear from Volta as XT2AW Sep 16-18, then from the Cameroons TJ and finally his last two days Sep 21 and 22 from Gabon. He returns to Germany Sep 24. QSL to DK9KD for all.

Vince Thompson, K5VT, back in the States, says his 3V8VT operating was 20 Meters only due to antenna limitations, but he is hinting another stop in Tunisia may not be far off, and if so he will be prepared for all bands at that time.

Rumors concerning Albania now seem to center around EA5AK, who claims to have a license for ZA2HAM valid Dec 4-14 of this year. Other Spanish hams continue to be mentioned in connection with the effort.

Following their successful Juan de Nova operation, FR0FLO and F6IRP made a surprise appearance from Mayotte on their way home, signing FH0FLO; the operation seems to have run only a day or so.

A commemorative operation is planned from Hawaii's Pearl Harbor, to sign KH6SP Dec 4, 5, and 6.

ZD8TC is up to his ears in alligators on 160 Meters...Tom, whose technique is to call stations he hears on their frequency on Top band, finds that although East Coast U.S. stations are putting big signals into Ascension, they don't seem to hear him. Yet, when he does work someone he gets a good report. Perhaps those alligators have migrated down from 50 MHz; Tom also see some big signals are coming out of the States on 6 Meters, and he has been able to work a few of them.

he DXCC...it has been announced that ARRL's Headquarters Awards Committee will be setting a date (apparently a future rather than retroactive one) after which credit for single-mode awards will be given only for QSLs which clearly state "2-way QSO." As it takes several months for a formal announcement to appear in QST, a guess might be January 1, 1982 for the new rule.

That Bangladesh rumored for early this month may actually happen, but the dates are October 13-18, according to JA8CXE of the "JA8 DXGroup." They don't have a callsign yet. JH2HDK is the group leader, and will be accompanied by JA8MWU and several others, who will share operating chores on 80-10 Meters and possibly 50 MHz, CW and SSB.

Terry Baxter, N6CW, and friends will operate from Tortola, British Virgin Is., again this year for the CQ Phone Contest. This will be Terry's sixth straight effort from there (he is VP2VDM).

And St. Pierre will again be the destination of W8AH Oct 10-18, in the company of K8CJQ, W8HR, and W8NZJY. They will be on 80-10 Meters, no lists.

In Issue 107 mention was made of the ARRL Roanoke Convention later this month, and of a slide show on the 1980 PJ2CC CQ WW Phone Contest operation. That multi-multi operation was the 1980 top score but not an all-time record. That honor still belongs to the 1979 VP2KC multi-multi. Sorry.

What has happened to YI1BOO and LU3ZY on South Sandwich? Anyone know? No reports of either of these stations in some time. Many still need.

160 Meters is already getting very good in anticipation of the Winter DX season; VK and ZL stations have been coming through to the East Coast U.S. around 0400Z. At the same time, 10 Meters, at the other end of the spectrum, continues its stumbling act toward autumn propagation. For example, last weekend in the Worked All Europe 'test, 10 was excellent the first day but on Sunday only USSR stations had decent signals.

And as K5RC observed in a recent issue of the National Contest Journal, 160 is going to be very interesting this year with KWs allowed; now we will see who was playing fair in the past and who wasn't!

A number of inventions were made and hams contributed greatly to the art of communications. Quite often seemingly impossible things were done. This is the true nature of amateur radio—experimenting. These people appreciate the privilege of being able to communicate around the world and want to preserve and not to destroy it. They are self-policing and stick to the rules, regulations, and ethics. They are always gentlemen. They are not afraid to experiment.

This spirit is still alive and I had the pleasure to experience it during my visits while I was down in W-land. The "Old Ham" has some sort of home-brewed antenna, a scrounged tower, and good equipment which is quite often modified commercial or home-brewed. He is keeping up to date with technology and that gives him the edge in the pileup: His receiver has better selectivity and his antenna gives him an extra dB or two. This is what makes the Old Ham: experience and equipment. He hates lists because they are degrading the whole idea of the DX sport—chasing and nailing the DX.

It is a pleasure to meet such a bunch, because you can talk about all the aspects of ham radio and share your experiences. Among others, my hosts included Bob K2US, who is experimenting with antennas and decided to try one of the VE3BMV razor beams; Gary K2UU, who enjoys working on antennas, working DX and contests, and is involved with the big multi-multi station of K2GL (better known as N2AA); Ovie N2AJ, who is more technically-oriented; and Jack W2LZX, president of the LIDX Club and an old DX tiger. You can see that they can get excellent stations going by using their skills and experience when there is a lack of funds. In DXing, you can make up for the deficiencies in finances either by spending a little more time or by building and modifying equipment. A number of remarkable installations are around which rival some commercial radio stations. People such as K2GL, W2HCW, W2PV, KØRF, ABØI, and N5AU, to name a few, have stations which show a lot of work, love, and persistence. It is a sheer pleasure to talk to people like them. Because they love their hobby, these "well-cooked" hams work at it and enjoy it.

CHINA BREAKTHROUGH

The Boeing Employees Amateur Radio Society (BEARS) delegation arrived in the People's Republic of China on September 4, 1981, and departed on September 12. We were the first official international amateur radio delegation to visit China in more than 32 years. Our host was the Chinese Institute of Electronics, a branch of the 4th Ministry of Machine Building. The delegation members consisted of Pat West W7EA, Henry Oman K7HO, Bob Hudson K7LAY, and Bill Showers KC7CF.

Sponsors included Boeing and the Western Washington DX Club. Contributors to our expedition included the R.L. Drake Company, which supplied two complete TR7 stations, Telex/Hy-Gain, which supplied two dipole antennas, and the ARRL, which supplied a copy of the film "Wide World of Amateur Radio" and a few books.

Our delegation prepared and presented a four-hour slide presentation covering amateur radio in the USA. This presentation was made in each of the cities that we visited.

Although we did not expect to operate, we were permitted to set up a demonstration station in Beijing and communicate with our home city, Seattle. This historic event occurred at about ten pm, Beijing time, on September 6th. Our contact in Seattle, representing our two clubs, was W7PHO and our callsign in Beijing, also representing our two clubs, was K7LAY. We are very sorry that we could not talk to more stations.

The Chinese advised us that our transmissions were the first authorized amateur radio communication demonstration in more than 32 years—truly an historic event. This contact signifies the increasing friendship between our two nations.

A second historic event occurred on September 9th. With the assistance of our delegation in Shanghai, the Chinese in Beijing installed a Drake TR7 station and the Chinese in Shanghai also installed a Drake TR7 station. Successful communications were established between Beijing and Shanghai by Chinese operators, again for the first time in more than 32 years.

The operator in Beijing was Chen Ren-Mo, and the operator in Shanghai was Hsu Y.C. Mr.

Hsu was licensed many years ago as XU8CH and C1CH.

Although propagation was not good between the cities, communications were established about 10:45 pm on September 9th. The station in Beijing used the callsign CIE and the one in Shanghai used K7LAY. Both stations were heard in many countries with strong signals. The Chinese asked us to tell the world that their top government leaders are solidly behind amateur radio, and that before too long, China expects to establish many friends throughout the world through the medium of amateur radio.

Our delegation was overwhelmed by the reception we received in China and very honored to be the first official amateur radio delegation to China and to demonstrate amateur radio. In China, we met many old-timers and our meetings with them were precious events in all our lives.

We are very appreciative of our host in China, The China Institute of Electronics, and also the China National Radio Sport Commission and the Shanghai Institute of Electronics.

Editor's Note: This report is based on a press release from the US delegation, filed on September 12 in Hong Kong. *73* hopes to be able to report more details on the China breakthrough in the months to come.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

I've lost track of the number of times we've asked everyone to send in their information as early as possible, but I thought I'd better do it one more time. At least three or four contest announcements were received too late for the last issue. Some came as late as four weeks past deadline. Just to show you what kind of lead time is involved, the material for this issue had to be in my hands no later than September 20th. To be safe, it should be sent directly to my home address and not through the magazine as that only tends to slow things up. It might be several weeks before mail is forwarded to me from Peterborough. If material is coming from overseas, send it as early as possible and use air mail to avoid delays. In all cases, try to get the information in as early as possible.

In the results department... W1CCN finished third while K2SX finished fifth on CW during the 1981 RSGB 7-MHz Contest. They were the only USA amateurs listed in the official results. Maybe we can do a little better in '82.

CONNECTICUT QSO PARTY

Starts: 2000 GMT December 5
Ends: 0200 GMT December 7
Rest period: 0500 to 1200 GMT December 6

Sponsored by the Candlewood Amateur Radio Association (CARA). Phone and CW are considered to be the same contest. Stations may be worked once on each band and each mode.

EXCHANGE:

Send QSO number, RS(T), and ARRL section or Connecticut county.

SCORING:

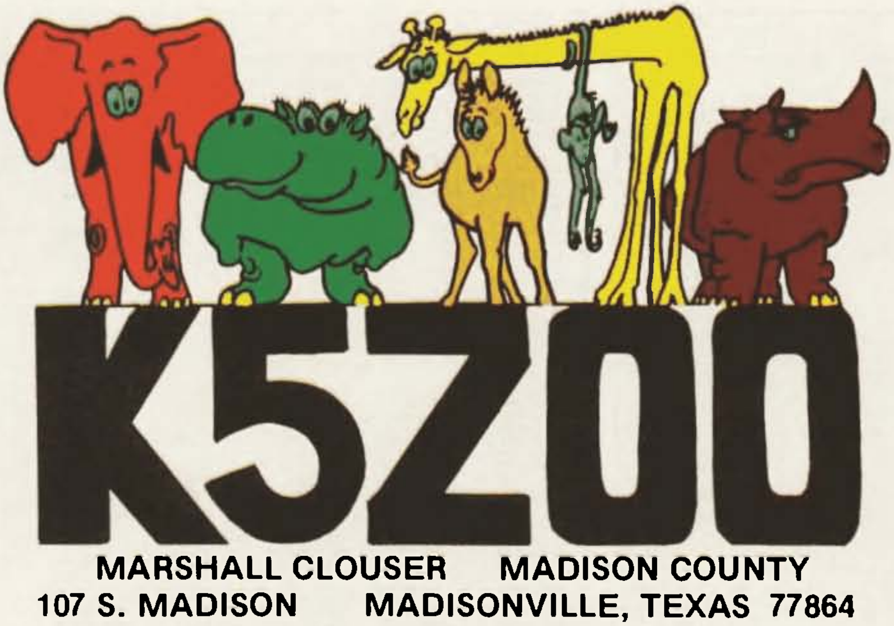
Out-of-state stations multiply total QSOs by the number of Connecticut counties worked (8 maximum). Connecticut stations multiply total QSOs by the sum of ARRL stations and provinces. Additional DX contacts count for QSO points, but only one DX multiplier overall is allowed. W1QI, the club station, will be operating CW on the odd hours and SSB on the even hours and counts as 5 points on each band and mode. Novice contacts count as 2 points each and OSCAR contacts count 3 points each.

FREQUENCIES:

CW—40 kHz up from the bottom of each band; SSB—3927, 7250, 14295, 21370, 28540; Novice—3725, 7125, 21125, 28125.

ENTRIES & AWARDS:

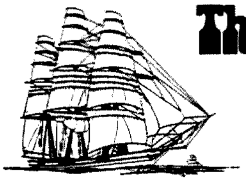
A Worked All Connecticut Counties certificate will be awarded to each station working all Connecticut counties. Other awards given as usual, minimum of 5 QSO points! Logs must show category, date/time (GMT), stations, numbers,



QSL OF THE MONTH

Bright, eye-catching color and humorous graphics made K5ZOO's card this month's winner.

If you would like to enter the contest, put your QSL in an envelope and mail it along with your choice of a book from *73's* Radio Bookshop to *73 Magazine*, Pine Street, Peterborough NH 03458. Attention: QSL of the Month. Entries which do not use an envelope (the Postal Service does occasionally damage cards) and do not specify book choice will not be considered. Each month we consider a new set of entries, so you may want to resubmit your card in another month.



The Scuttlebutt

yankee clipper contest club

NEWSLETTER CONTEST WINNER

This month, we salute the Yankee Clipper Contest Club (YCCC) and its publication, *The Scuttlebutt*. Despite the limitations of a small budget, editor K1GQ produces a good-looking, information-packed, 10-page newsletter each month. What's the secret of this low-cost success?

For starters, the editor leaves no stone unturned in his quest for club members with connections necessary to get *The Scuttlebutt* printed at the lowest possible cost... sometimes for free! Occasionally, he cajoles a local firm involved in the ham business to pick up the tab, in exchange for a page of advertising.

Typesetting for *The Scuttlebutt* is a volunteer effort, contributed by club members with access to the required equipment. Mailing labels are similarly handled by a member who keeps the YCCC membership list on the computer in his office.

The editorial content of the newsletter is a cooperative effort, too, with many club members helping out. The editor doesn't try to write the whole thing.

The lesson to be drawn from *The Scuttlebutt* is that there are numerous untapped resources both within your club and within your community. Editors on a budget (aren't we all?) must seek out these hidden assets. Quality on a shoestring—it *can* be done!

Proud of your club's newsletter? Send it to: Newsletter Contest, *73 Magazine*, Peterborough NH 03458.—WB8BTH.

bands, QSO points, and claimed scores. Enclose a large SASE for results. Logs must be postmarked by January 2nd and sent to: Steve Grouse KA1ECL, 3 Queens Court, Danbury CT 06610.

G-QRP-CLUB WINTER SPORTS

Daily from 0900 to 2300 GMT
December 26 to December 31

All amateur radio operators interested in QRP are invited to take part in the club's activity. No special exchange information was mentioned in the information provided by the club. The operating schedule for each day is as follows:

- 3560 kHz—1200-1300, 1400-1500, 2100-2200 GMT.
- 7030 kHz—1100-1200, 1300-1400, 2000-2100 GMT.
- 14060 kHz—0900-1000, 1730-2000, 2200-2300 GMT.
- 21060/28060 kHz—1000-1100, 1500-1730 GMT.

Reports on the Winter Sports Activity should be sent to Gus Taylor G8PG, 37 Pickerill Road, Greasby, Wirral, Merseyside L49 3ND, England.

CANADA CONTEST

Starts: 0000 GMT December 27
Ends: 2359 GMT December 27

Sponsored by the Canadian Amateur Radio Federation (CARF), the contest is open to all amateurs. Use all bands from 160 to 2 meters, CW and phone combined, and everybody works everybody. Classes of entry include: single operator, all band; single operator, single band; and multi-operator, single transmitter, all band. All contacts with amateur stations are valid. The same station may be worked twice on each band, once on CW and once on phone. No crossmode contacts and no CW contacts in the phone bands allowed.

EXCHANGE:

Signal report and consecutive serial number starting with 001. VE1 stations will also send their province (NS, NB, PEI).

SCORING:

Ten points for each contact with Canada, 1 point for each

contact with others. Ten bonus points for each contact with any CARF official station using the suffix TCA or VCA. Multipliers are the number of Canadian provinces/territories worked on each band and mode (12 provinces/territories x 8 bands x 2 modes for a maximum of 192 possible multipliers).

FREQUENCIES (as applicable):

Phone—1810, 3770, 3900, 7070, 7230, 14150, 14300, 21200, 21400, 28500, 50100, 146520; CW—1810, 3525, 7025, 14025, 21025, 28025, 50100, 144100. Suggest phone on the even hours (GMT), CW on the odd hours (GMT).

AWARDS:

The CARF Canada Contest Trophy will be awarded to the highest scoring single operator entry. Certificates will be awarded to the highest score in each entry class in each province/territory, USA call area, and DX country, and to the highest score from those who have only their amateur certificates.

ENTRIES:

A valid entry must contain log sheets, dupe sheets, and a summary sheet showing a chart of multipliers per band/mode and score calculation. Send your entry with comments to: Canadian Amateur Radio Federation, PO Box 2172, Station D, Ottawa, Ontario, Canada K1P 5W4, postmarked within one month of the end of the contest. Results will be published in *TCA*, the Canadian amateur magazine. Nonmembers may include an SASE for a copy of the results.

ZERO DISTRICT QSO PARTY

Starts: 2000 GMT January 2
Ends: 0200 GMT January 4

Organized by the Mississippi Valley Radio Club. Stations outside of Zero District will work Zero stations only. Zeros may work any station. The same station may be worked once on each band and each mode. However, stations in the special mobile class may be worked each time they change counties.

EXCHANGE:

RS(T) and ARRL section. Zero District stations must also send county.

FREQUENCIES:

3560, 3900, 3725, 7060, 7270, 7125, 14060, 14300, 21125, 21060, 21370, 28125, 28060, 28570.

SCORING:

Add the number of Zero District ARRL sections worked plus the number of Zero District counties, then multiply by the number of contacts. Zeros score by adding ARRL sections, Zero District counties, and DXCC countries worked and then multiplying by total contacts.

ENTRIES & AWARDS:

Certificates will be issued to all entrants who submit a log and SASE. Endorsements will be given for high score in each ARRL section, DX country, Novice/Technician class, and Special Mobile class. Mail logs by February 15th to WØSI, 3518 W. Columbia, Davenport IA 52804. Include an SASE for log forms or results.

HAM HELP

I need an i-f transformer for a Hammarlund HQ-170 receiver. It is designated T1 on the schematic, and is Hammarlund part #K26402-1. It is a combination 455-kHz and 3035-kHz transformer that needs an exact replacement. I will gladly pay a reasonable price for a suitable transformer.

David Hansen KB6FI
7484 Tustin Road
Salinas CA 93907

Information and/or schematics wanted for conversion of Drake L-75 linear to 10 meters. Will defray all costs involved.

E.V. Schoonmaker N5CGE
792-A Fairview Avenue
Annapolis MD 21403

Wanted: work in Knoxville or Chattanooga, Tennessee, area. First class radiotelephone and Extra class license.

H.F. Schnur
115 Intercept Ave.
North Charleston SC 29405

I am in need of the following items: (1) manual/schematic for Hallicrafters HT32B; (2) a main power transformer for the HT32B (please state price), and (3) a manual or schematic for the Globe Electronics Hi-Bander VHF-62 transmitter.

I will pay for postage and copying costs.

Richard E. Duell W9LSD
4415 N. Florence Dr.
McHenry IL 60050

I am trying to locate an instruction manual and schematic diagram for a Model Memo 512 keyer made by K. E. Electronics.

I will pay for copy or copy and return original.

William Hartley K2RDS
1201 Paul Ave.
Schenectady NY 12306

I am in need of a Centralab switch, #PA-076. I'll be glad to pay for it.

Don Ramey WA4FQC
Box 217
Meridianville AL 35759

I need an antenna relay for the Hammarlund HX-50 transmitter. Also, information about any source for Hammarlund parts will be appreciated.

Arnold Irvine KAØELN
5 Drumcliffe Drive
Warren PA 16365

Please: I need the manual for a Peirson KE-93 receiver and an Elmac AF-67 transmitter. I will copy and return and pay mailing costs.

Robert F. Voelker WA2PCL
101-23 Lefferts Blvd.
Richmond Hill NY 11419

I am looking for a UA1LO QSL card from before 1968 for my astronaut autograph collection. (UA1LO was Yuri Gagarin, the first man in space.) Thank you.

Mike Smithwick AA6XI
25215 La Loma Drive
Los Altos Hills CA 94022

I am looking for a book or information on a 2-meter rig, the Setec-Elect FRT-203. It's an 8-channel rig and I have no idea who made it.

F. Whittier WB1CXX
RFD #1, Box 390
Madison ME 04950

STATEMENT OF OWNERSHIP, MANAGEMENT AND CIRCULATION (Required by 39 U.S.C. 3685). 1. Title of publication, *73 Magazine*. 2. Date of filing, Oct. 1, 1981. 3. Frequency of issue, Monthly. A. No. of issues published annually. 12. B. Annual subscription price, $25.00. 4. Location of known office of publication (Street, City, County, State and ZIP Code) (Not printers), 80 Pine Street, Peterborough, Hillsboro County, N.H. 03458. 5. Location of the headquarters or general business offices of the publishers (Not printers), 80 Pine Street, Peterborough, Hillsboro County, N.H. 03458. 6. Names and complete addresses of publisher, editor and managing editor. Publisher (Name and Address), Wayne Green, Peterborough, N.H. 03458. Editor (Name and Address), Wayne Green, Peterborough, N.H. 03458. Managing Editor (Name and Address), Jack Burnett, 12-C Granite St., Peterborough, N.H. 03458. 7. Owner (If owned by a corporation, its name and address must be stated and also immediately thereunder the names and addresses of stockholders owning or holding 1 percent of more of total amount of stock. If not owned by a corporation, the names and addresses of the individual owners must be given. If owned by a partnership or other unincorporated firm, its name and address, as well as that of each individual must be given. If the publication is published by a nonprofit organization, its name and address must be stated.) Name, 73, Inc., Peterborough, N.H. 03458. Wayne Green, Peterborough, N.H. 03458. 8. Known bondholders, mortgagees and other security holders owning or holding 1 percent or more of total amount of bonds, mortgages or other securities (If there are none, so state) Name, none. 9. For completion by nonprofit organizations authorized to mail at special rates (Section 132.122, PSM) The purpose, function and nonprofit status of this organization and the exempt status for Federal income tax purposes (Check one) Not applicable. 10. Extent and nature of circulation. (X) Average No. copies each issue during preceding 12 months. (Y) Actual No. copies of single issue published nearest to filing date. A. Total No. of copies printed (Net Press Run) (X) 70,810 (Y) 69,253. B. Paid circulation 1. Sales through dealers and carriers, street vendors and counters sales, (X) 11,964 (Y) 15,186. 2. Mail subscriptions (X) 52,747 (Y) 51,871. C. Total paid circulation (Sum of 10B1 and 10B2) (X) 64,711 (Y) 67,057. D. Free distribution by mail, carrier or other means, samples, complimentary, and other free copies (X) 359 (Y) 460. E. Total distribution (Sum of C and D) (X) 65,070 (Y) 67,517. F. Copies not distributed 1. Office use, left over, unaccounted, spoiled after printing (X) 5,024 (Y) 1,020. 2. Returns from news agents (X) 716 (Y) 716. G. Total (Sum of E, F1 and 2—should equal net press run shown in A) (X) 70,810 (Y) 69,253. 11. I certify that the statements made by me above are correct and complete. Signature and title of editor, publisher, business manager, or owner. Debra Boudrieau, Business Manager.

W2NSD/1
NEVER SAY DIE
editorial by Wayne Green

from page 8

development. In the past I've found older amateurs are generally resistant to new ideas and really hate to have to read about them. But after a while, though I lose readers in the process, interest does come and finally the other amateur publications reluctantly join me in publishing information on the new technology. It worked this way with sideband, with transistors, with ICs, and with FM, so we'll probably see the same pattern.

There are, obviously, far more benefits than just a wonderful emergency communications system which can come from this step ahead. If we are successful in establishing a system for getting the growth of amateur radio that we really need... and that will be on the order of 33% per year, not 3%... we are going to have to develop much more efficient communications modes. Anyone listening to the high end of twenty-meter phone any evening has to realize that new techniques are already needed... seriously needed. With high-speed ASCII communications, we could easily accommodate a thousand stations where we now have one and we could have room for the two million hams we should have right now and the three million we want to have by 1990.

This is a reasonable answer, too, for using the narrow bands available on our ham satellites.

If we develop the encoding techniques I discussed at the last NIAC meeting, our information exchange would immediately go from 8500 words per minute to about 26,000! All this would be done via a simple integrated circuit chip which would encode the 32,000 most used words before sending them... and then decode them upon reception. Further, the output could be in *any* language, allowing amateurs anywhere in the world to communicate with each other, regardless of their spoken language. Again, nothing has to be invented. We just have to write the computer programs to accomplish this and perfect our equipment, techniques, and protocols.

A word of warning, if I may. If we are going to turn around the disaster which has brought us to technological defeat at the hands of the Japanese, we are going to have to do more than nod our heads and adjourn until the next scheduled NIAC meeting. If we are going to be able to provide anything of any great value in the way of emergency communications ... if we are going to develop the systems which I have outlined... we need to really activate NIAC, using its communications with the FCC to bring this situation to the attention of the White House.

By the way, speaking of satellite communications: If we were to dedicate one channel of a satellite to a calling frequency, it would, using 9600 baud, be able to handle 216,000 different calls per hour for us, with each call consisting of the callsign of the station called and the calling station.

In terms of emergencies, tests have already been made which show that we can use relatively low-powered emergency transmitters, and by measuring the signals received through a ham satellite, it is possible to determine the location of the transmitter to a surprising degree. Digitizing and automating this service would provide an emergency locating system which would be simple and inexpensive and work anywhere in the world... whether it be used to locate a raft floating in the Pacific Ocean or someone lost in the jungles of Sumatra. It is the digitizing and automation which bring this emergency service to anyone who needs it.

So here we are, on the brink of yet another revolution in communications. Will this be brought about by amateurs or must we wait for commercial and military systems to do what we could develop? A good part of the answer for that lies, in my estimation, in whether we as a group will be able to start some action with the FCC and with our government which will result in a sudden and spectacular growth of amateur radio.

Most of you who are here today have made long trips and have to leave your businesses. You've carried the expense of this yourselves. Now, while it is obviously an honor to be a member of a government advisory committee, it is an empty honor... worthy of no more than a line in a *Who's Who* biography which will be read by few... unless we are able to actually accomplish something.

As the *only* official interface between the amateur radio community and the FCC, we have a responsibility to our fellow amateurs to speak up for them. As the group which I feel must shoulder most of the responsibility for the loss of our country's technological leadership of the world, we should speak up for radio amateurs and do our best to see that the FCC provides the incentive for amateur radio to grow again. We have to remember that even if we are able to spark a combination of events which gets amateur radio into a growth pattern which is three times our past highest growth, it will still take us at least ten years to catch up with the catastrophic losses we have suffered over the last 18 years.

I believe that the FCC commissioners will be interested in this situation and be responsive to our leadership, if we can provide it... and that, at the root of it, is the real purpose of this committee.

I suggest that we need more than an occasional meeting and minutes, more even than a report and recommendation. I suggest that we appoint an action committee to work with the FCC to develop both White House interest and the rules changes which might contribute to the goals we have in mind.

Since my business is growing at an ever-increasing rate, now numbering eight monthly publications plus a software publishing division, and with five more monthly publications in prospect, plus the opening of at least three more major divisions of the company, my own time is severely limited. I would be happy to serve as a member of an action committee, but I would not be able to provide the leadership and time that a chairman should devote to such a committee. Between my ham interests and my computer interests, I spend a good deal of time traveling. Last month I managed to get on the air for a short while as W2NSD/3D6, W2NSD/ZS, and as 7P8CA, all while setting up South American and South African editions of one of my computer magazines.

I did manage, just before leaving for Africa... and just after a trip to California setting up three prospective new publications... to visit with FCC Chairman Fowler and discuss briefly some of the ideas which I have just covered. I found him most enthusiastic and cooperative... so I believe that if NIAC will appoint a subcommittee, an action subcommittee, we will be able to more than be rewarded for our time and money spent as members of NIAC.

The job of such a committee and of the FCC is not an easy one. The polls of amateurs have shown clearly the strong feelings for maintaining the Morse-code requirement. Yet when one talks to people interested in becoming radio amateurs, this is always the major obstacle. Indeed, between the wealth of destructive code teaching systems now available and the ability of even the best of us to put off an unpleasant job if at all possible, it is a wonder that we have even maintained our present membership.

As I have mentioned in the past before this committee, I think I have heard every argument, both pro and con, on the subject of the code requirement for our amateur licenses. It is my belief, after giving consideration to all of these arguments, that we should have a technical license exam, not one measuring a skill. I see not even the remotest connection between a skill of copying code and being a good amateur. Despite the attempts of the plain language proposals, I tend to define a good amateur as one who is pursuing any or all of the four major reasons set out in our rules, 97.1, for the existence of the service.

It is increasingly difficult to remain blind to the success of the Japanese amateur radio system and I think we should put aside our "not invented here" emotions and take advantage of an innovation which has obviously worked. Just as American industry is taking the Japanese Type-Z management system seriously and finding that this brings about remarkable increases in productivity for their firms ... and a sudden drop in people changing jobs... we should look pragmatically at the Japanese no-code license system as a possible solution to our problems.

There will, I am sure, be resistance from older amateurs. I would be surprised if one or more of the ham magazines did not rush to take political advantage of the situation. But if we insist on trying to follow the system of doing only what the majority wants, we will have a technology as innovative as our television programs. This is a time for leaders... leaders with confidence. We have a good example of this in our Administration, which has not been afraid to push against the tide toward goals it sees as important in the long run. I am hoping that NIAC will form an action committee which can do likewise for the benefit of amateur radio and our country.

Despite my plea not to be made chairman of a committee to tackle the problem, the new chairman of NIAC, Charlie Dunn K7RMG, immediately established an Action Committee and made me chairman. I was serious about already having enough to do and was not pulling the old briarpatch tears. Well, okay, I'm chairman of a committee, and I'll do the best I can to get it organized and into action.

The goal of the Action Committee is to work with the FCC to establish a growth of amateur radio such as we have never seen before. I feel, as I said in my report, that we should aim at no less than a 33% growth per year and keep that up for a least ten years.

Another task of the committee is to work with the FCC to set up some system whereby amateurs can experiment and develop new modes of communications such as digital high-speed interactive networks as cited in my report.

Obviously, we have our hands full, so it is going to take a lot of work and cooperation with this committee... which consists of Dorhoffer of *CQ*, Imlay of *QST*, Curtis (who publishes books in the computer field), Harold Todd W7ZXM from Seattle, and me as chairman.

If you have spent any time mixing with would-be hams, you know as well as I that our Morse-code requirement is probably the major single obstacle which has been keeping down our growth. Yes, I know that most old-time amateurs are fiercely adamant about keeping the code test. But as I mentioned in my report, it has been years since I have heard a new argument on the subject and the balance, as far as I can see, is to-

wards making this a technical hobby instead of a skill hobby.

Some of the wheezes which come to mind are as follows:

1. *Code is a ham heritage.* So is QRM, but that's no reason to keep it. I am convinced that we will have more CW operators than ever if we make it a fun part of hamming instead of obligatory. Besides, with more and more operators using Morse keyboards, what do you mean by heritage? Those keyboards and Morse code readers are selling like crazy...if that tells you anything.

2. *Without the code test we'll be swamped with lousy operators.* Oh my goodness, since when did learning the code make anyone a good operator? If you want to hear really good operating, not the jamming and pileups we indulge in here, listen to the Japanese operators. They were taught how to operate by their clubs but had no code test.

3. *In emergencies, code can get through when phone can't, so everyone should know the code.* Well, that may have been true 50 years ago, but today most of your emergency traffic is on phone...and sideband gets through as well as CW almost anytime. In the future, we will be running most emergency traffic over high-speed digital networks, not on code or phone, anyway.

4. *CW rigs cost less than phone equipment, so by emphasizing code we are enabling even the poor amateur to participate.* In the pre-war years we could buy this baggage. When Heath brought out the HW rigs, that argument went out the window...where it still lies...and that was about 20 years ago. Let's try to get out of the past.

5. *With the current exams made stupidly simple by cheat books such as the ARRL Q & A* Manual *and the Bash books, we have to have SOMETHING to keep everyone out.* I partially agree...but let's make it something better than the Morse-code test. Perhaps we could change to a licensing system whereby new amateurs would have to qualify before a club board, showing that they know the rules and are able to operate a ham station. We might make the technical exam less vulnerable to circumvention by League and Bash Q & A books.

6. *If we don't keep the code in the ham test, code will just die out.* As I said, I think that once it is made fun instead of punishment, we will find a new enthusiasm for the skill. Our clubs and publications can intensify this with contests, certificates, and articles on the subject.

7. *Just because the Japanese have had such incredible success merely by removing the code requirement is no reason why we have to imitate them.* Well, I believe in learning. When someone does something new and it is a success and what I'm doing is an obvious failure, it is time to re-evaluate and not let *Not Invented Here* stop me.

8. *I had to go through all that misery, so why should I want anyone to have it easier than I did?* Golly, I don't have any real answer to that bit of garbage.

9. *Suppose you are stuck in a life-and-death situation where all you have is a CW transmitter for communications?* Having been in just such a situation, and having used CW to save 85 lives, my answer is that the likelihood of such a situation occurring is so remote that I really wonder if it is worth sacrificing the technology of America on such a remote circumstance.

Yes, I know that there will be crowds of old-timers at Dayton looking for me with ropes, tar, and feathers. Well, I've leveled with you down through the years, never taking the easy way out. In this case, I think it is time...way past time, actually ...to get serious about revamping our ham exams and making our hobby a technical one rather than one limited mostly by an easily learned skill.

Think of it like this. Sure, you and I know that it is not difficult to learn the code. Piece of cake, really. But you also have to admit that when you talk with nonhams, you probably make a big deal of it. If you put yourself in the shoes of someone considering being a ham, you will see, as they do, that the Morse code is a terrifying new language...one which they are not at all sure they can master. This fear is in itself enough to turn tens of thousands away from amateur radio each year.

Then, when someone decides that he or she is going to try anyway, the fear is enough to put off practice. Remember that nowhere in our magazines or in talking with amateurs is any reference made to code being fun. It is the major hurdle for newcomers and we make a big deal of it as such. So our talking generates terror in the hearts of newcomers and makes practice all the more difficult...even impossible. They *know* they are going to fail...and they find this self-fulfilling.

I've talked with thousands of people who wanted to be hams, but who were unable to surmount the code requirement. Most of them seriously tried but were conned into using a terrible code course and found themselves failing at it no matter how hard they tried. Indeed, many of the code courses are ridiculous...including the best-selling one of all. This single code course probably has lost us more hams that we've gained in the last twenty years.

In speaking out against the code requirement, perhaps I am sowing the seeds of my own losses. The *73 Magazine* code course, while it sells far fewer than does the ARRL series, has sold about 25,000 cassettes a year. Will I be out of the code cassette business if we get rid of that element of the license? I think not...in fact I'm betting that I'll be able to sell more than ever...as fun.

The recent *QST* polls showed that *QST* readers overwhelmingly are in favor of keeping the code requirement, so it's Wayne Green against the world again. *QST* has been pushing code for as long as I've been hamming—over 40 years. This got them into trouble in the late 40s when a large percentage of the amateurs deserted the League to go with the National Amateur Radio Council...a phone-oriented group which got us expanded phone frequencies on 75m, the 40m phone band, and more frequencies on 20m...over a lot of dead bodies. NARC, achieving its goals, went away.

So, if anyone has any other arguments which I have not enumerated, I'll be glad to publish them, along with my ripostes. Let's get this out in the open and fight fair on it...not let prejudices left over from 50 years ago continue to stop our growth. When I first got into amateur radio, there was still a lot of smoldering anger over being forced off spark. Then I watched the same thing happen with AM phone. I believe in being conservative, but there is such a thing as carrying it too far. If you disagree with me, I ask you to fight fair. If you agree with me, fight with me for the growth and health of the very best hobby ever invented.

FCC CASH-FLOW PROBLEMS

With the Reagan administration shaking every federal agency to reduce expenses and lay off people, the FCC...which has been underfunded for years ...is in particular trouble. Indeed, if they had not been so prudent in the past, they would be far better able to weather the current storms.

There has been some talk of getting government agencies to charge for services so they can get into the black. If this talk persists, we may again see a charge for ham licenses. Since amateur radio takes up a miniscule amount of the Commission's time, our charges should be minimal, as they were the last try. But I think I have some ideas which might cut the cost of the amateur service even further for the Commission.

A large percentage of the Commission time and money is spent on commercial broadcasters, so there is adequate reason to pass along this cost to them. After all, *they are* making a living out of the FCC work. I'd also like to see the common-carrier chaps pick up their end. It's about time...the television broadcasters using this service kind of snuck in through the back door. Indeed, I haven't seen any legal justification for them being allowed to use common-carrier channels for television. That service was not designed for that use and, as far as I know, it was never authorized for that. Well, let's see that go through the legalities and be made official...with the common-carrier boys picking up the full tab.

Perhaps I'm being a bit vindictive because this bunch of crumbs cost *73* tens of thousands of dollars in legal fees to fight their suit against us. A suit found without merit, which I feel was brought merely as an intimidation to try to prevent *73* from publishing 2300-GHz articles. I suspect that more is accomplished in our country via the threat of court cases than through the cases themselves. I know that few firms are large enough to absorb the costs the CCAT people put us through, and most would have shut up and blown away. I

happen to think that freedom of the press for amateurs to learn about these things is worthy of such an investment, so we put up the money needed to fight these stinkers.

Getting back to the FCC problems. During the Carter administration, the FCC commissioners were so upset over amateur radio as a result of the hearing over linear amplifiers that they virtually eliminated the division. Now what's left of the amateur division has to face across-the-board budget cuts. For those readers who are forgetful or inattentive, let me remind you that this alienation of the Commission came about entirely needlessly. It was the testimony of one amateur which did it... and he was representing a well-known group. He stood up there and insulted the new commissioners, putting us all in the doghouse for four years.

We have a new chairman of the Commission and several new commissioners, so we have a chance for a fresh start.

There are three ways in which amateur radio is costing the FCC money these days. One is the cost of giving license exams and issuing licenses. A second has to do with monitoring our bands. A third is the cost of handling our requested rule changes.

On the first item, I think we could set up a system which would cut their expenses enormously. I've written about this before, but not recently. What I would like to see is a system whereby qualifying radio clubs would be permitted to give license exams. In order to get around hokey pokey, I would suggest that there would have to be three licensed amateurs present during any test administration.

This could be almost completely computerized as far as the Commission is concerned, with machine-readable cards being sent in by clubs for the issuance of the licenses. This would enable field offices to cut back substantially on personnel no longer needed to give and monitor these tests on a regular basis.

This would enable almost every hamfest to have a licensing session, run by a local qualified ham club. It would further cut the cost for people wanting ham tickets since they no longer would have to make the long trip (for many) to a city having an exam center and lose a day or two of pay in the process. Most exams could be given at night or on weekends, at the convenience of the examinees and the club.

By automating the process, the FCC wouldn't even have to have data entry people at Gettysburg to enter the names and addresses of the licensees. This would be a further savings for them. And this move ahead toward automation would set the stage for almost instant licensing. The next step would be sending in the information over the telephone via a data terminal (or any microcomputer with a modem...which just about every club has at its disposal). The exams could be given, the data typed in at the club, sent by modem to Gettysburg, and instantly confirmed, along with the new call of the licensee. Gettysburg would forward the data to Washington, where the actual license would be printed out and mailed, much as is done at present.

If we get into a charge for our licenses, each club could set up an account with the FCC which could be debited each time a new license was issued by them. This would give the FCC a nice float with which to work. If we had, say, 5,000 clubs participating, with each depositing $500 (towards licenses at $10 each), this would give the FCC a two and a half million dollar float. That would earn them about $30,000 a month in interest at 15%. That in itself would pay the salaries of about 15 people at the FCC.

With membership to the League costing $25 per year, perhaps that is a more reasonable price for us to pay for our licenses. Certainly the benefits of our licenses are more than a club membership. That would put a price tag on a five-year license at $125, which might seem a bit steep for youngsters. Of course, we have very few youngsters coming in at the present cost (nothing), so it is difficult to get emotional over any drop that $125 might entail.

The fee would hit retired people hard...even though they seem able to come up with the money for the ARRL with no problem. It might come down to a choice between a license and a *QST* subscription.

So what would be reasonable for a ham license, considering where we are with inflation these days? If $25 a year is too much, how much isn't too much?

One way to look at this is from the other side. What is it actually costing the government to provide us with the license? Perhaps this makes more sense than going by how much it is worth to us...which is a lot in some cases...and not much in others. If we are able to help the Commission cut their expenses, we can rationalize paying less for the service we are getting... and that is the key, to my way of thinking. I don't mind paying *my* share. I don't want to pay the share for someone too lazy or cheap to pay, someone who wants to ride on my coattails.

If we are able to take the license examination administration off their hands, that will save them money. And, considering the usual government efficiency, cutting that expense at one end should save several times the cost by the time the whole organization is considered.

Then there is the matter of monitoring. Here we could certainly help and would benefit in several ways as a result. The benefits would be fantastic. First, we would stop hearing from the Commission that amateurs are not permitted to experiment with new modes of communications just because the FCC monitoring stations are unable to decipher our transmissions. That beauty of a rule...a rule, by the way, which was never written into any of our regulations, but was just decided unilaterally for us...has kept amateurs from developing any significant new modes of communications for the last twenty years or so. That has been one of the most destructive unwritten rules in the history of amateur radio, as well as a direct violation of 97.1c of our written rules.

Secondly, with a thousand amateurs available for monitoring for every present FCC employee, we could do a job of monitoring which would be almost infinitely better than is being done at present. I know there are thousands of amateurs who would jump at the chance to participate in such an operation. Indeed, amateurs could set it up, establish the computer communications which would make it work, develop automatic scanning equipment to monitor the entire spectrum, and so on. Between our retired hams, our handicapped hams, and the cooperation of several thousand ham clubs, we'd have a ball...and do a splendid job.

We also could save the FCC a bundle...passing along only those reports which were of importance to the few FCC monitoring stations still needed. You know as well as I that clubs would love to set up direction-finding systems to track down mysterious stations...to listen for emergency air or marine traffic...and so on. It would give us much more to do which would be both fun and beneficial to the country.

On the matter of cutting down on legislative expenses, let me bring up an idea which I have written about every now and then down through the last thirty years. This has to do with amateurs taking the responsibility for coming up with proposed rule changes...and working them out via a symposium similar to that run by the ITU in Geneva every few years. We could have as a responsibility for our ham clubs the generation and forwarding of proposed rule changes. Then we would have a meeting every two years where club delegates could discuss and decide what actual changes we really want.

We could, like the ITU, set up subcommittees to discuss and recommend action on each of the proposed changes. These committees would pass along their recommendations to a meeting of all club delegates for final voting and action. This process could save the Commission hundreds of thousands of dollars presently spent on trying to cope with proposed ham rule changes. It also would get us our rule changes while they are needed, not years later when they are a nuisance and long unneeded.

In these ways, we could get amateur radio off the back of the Commission, saving them most of their present amateur radio expenses. In return, our service would be much more flexible and able to grow and develop, keeping up with... and preceding...technology. I think we would start seeing inventions and pioneering of new ideas returning to amateur ra-

dio . . . with benefits to our country and the world.

It is a shame that in these days of digital communications amateur radio is held back by the FCC with the technology of twenty years ago.

CLUB RESPONSIBILITY

Just a few years ago, I ran a poll of ham clubs and found that only about 1% were spending time and effort to run ham classes to develop new Novices. Perhaps I got overly abusive about this in my editorials, but the response was good and we got to a point where over 50% of the ham clubs were running ham classes.

That seems to have dropped in recent months . . . probably due to the difficulty of finding candidates as interest in CB has diminished. Well, CB or no CB, we need massive numbers of new hams. You read about that in more detail in my piece about NIAC and its recent meeting.

Now, I can see where a small ham club, with perhaps a half dozen members, might have difficulty in developing the resources needed to teach new hams. But if there are any larger clubs which are not holding up their end of this, let's get going immediately. Get those classes started. There are plenty of teaching materials . . . and you have members who will help out . . . if you will get moving. I want to see our next poll show that over 90% of the ham clubs are generating new licensees.

What is a reasonable number of new hams to bring into the world? Well, since your club probably represents only about 25% of the available local amateurs in your area, at best, you should aim for at least matching the number of your present club members each year. We need an overall 33% growth per year in amateur licensees. If we are able to get 4,000 of our clubs to run classes, we need to generate 33 new hams per club this year . . . and 45 per club next year. Obviously it can be done . . . if your club will start doing it . . . and see that every other club in your area is working just as hard as you are.

FAKE QSL CARDS

The world of the DX Honor Roll is shaking as a result of the expose by W6NZX. In what appears to be a classic case of shooting the messenger, Bob has been singled out to be pilloried, thus making sure that no one else rocks the boat.

Since there is no known way to prevent cheating, either on the side of the Honor Roll amateurs or the DXpeditioners, perhaps it is time we gave some consideration to taking the heat off the whole situation by either getting rid of the lists in ham magazines . . . or making it purely a matter of "claimed" countries contacted. I hate to be the one mentioning this, but the whole matter is one of no importance whatever.

By attaching some importance to the number of countries contacted, we set up several undesirable effects. First, we have seen the development of a cult in amateur radio dedicated at almost any cost to staying on top of the list. This has gotten to unbelievable proportions, with the pursuit taking precedence over families and even over work.

As the importance has been magnified in the minds of the cultists, *any* stratagem has become accepted toward the goal of staying on top of the list. These chaps are well aware that many of the cards they have are fakes in one sense or another. Indeed, the awards committees know this too, but have played along with the cultists (whom *they* have generated), accepting fakes at face value when there was no question in their minds about the invalidity of the cards.

I've mentioned recently that I have a bunch of cards which I know to be fakes, but which I could submit for awards . . . and get them. I'm not talking about cards from almost unknown stations, but cards from some of the best-known DXpeditioners.

Now what is a "fake" card? As minds crazed with getting ahead of others on The List churn, more and more fakes appear. Some are transparent forgeries, where the cards have been turned out in a local print shop with not even an effort to copy the original. I used to get those in abundance when they were submitted for our Worked The World award. Fortunately, being active in working DX, I had the real cards on hand for comparison.

Others are copies of the real cards. Now how is a person checking through a stack of cards going to be able to tell the difference between the real card and an exact imitation? According to inside sources, the awards people have not figured this one out and so they have been accepting the cards at face value.

With QSL managers all over the place, there is no way for a QSL printer to know that an order for 500 cards is from a chap (or group) about to put them out as counterfeit cards. Most people who handle our QSL orders (and *73* turns out around a hundred orders a week) know nothing about amateur radio. They just set the type, proofread it against the order, make up the printing plates, print the cards, package them, address them, and ship them out. I'm sure that most of the QSL printers work pretty much the same way. It's mass production.

QSL managers, with thousands of blank cards, have often been known to hand out samples to friends. It isn't difficult to fill in a card and end up with something which is exactly like the real thing. With many cards coming in envelopes, even the lack of a postmark or QSL bureau stamp doesn't mean much. For the perfectionist, there are fake bureau stamps, brief notes from the real DX operator in answer to some question to provide the envelope . . . and so on.

It does appear that for many DXers there is more fun and work involved in fooling the awards people than in the chase of the DX. That has become a subset of the cult.

DXpeditioners who do their own QSLing have given little thought to the counterfeit problem and have often handed out souvenir cards to anyone asking. Many of these have been filled out later and passed through the awards people for full credit. I've visited a number of rare spots and often have handed my cards out as souvenirs at hamfests.

Some of the rarer spots from which I've operated are 3D6, 7P8, 5Z4, 0D5, JY, YA, EP, YK, 9N, VS6, HL, 3D2, FO8, FK8, 5W1, KS6, KC4, 4U, etc., so picking up a collection of my old cards could be of some help. You don't hear a lot of YA and EP stations these days.

Another type of fake card is the one from the DXpeditioner who isn't where he says he is. This type of cheating has been going on as long as I can remember. The first really wholesale case where I was shown proof of the cheating happened around twenty years ago and had to do with a chap operating out of a hotel in North Africa, signing the calls of one country after another as he went around on his imaginary DXpedition. He was saved the problem of getting licenses, travel expenses, sand in the rigs, and other unpleasantnesses of West African travel through the expedient of not bothering to move. This was an inexpensive and creative solution to what otherwise would have been considerable aggravation. The cards are still acceptable for awards.

The ruse was so transparent that it took no time at all before other hams were using it and expanding upon it. This was a far simpler and cheaper way of getting to those out-of-the-way islands . . . of operating from unfriendly countries. During the 60s, all of us DX hunters built up our collection of fake cards. The awards managers were well aware of what was going on, but didn't want to upset things by refusing to accept the cards, so a conspiracy of silence developed. The rules were tightened a bit to make blatant cheating more difficult.

Miller and his cohorts pushed things too far for even the conspiracy of silence to swallow. Of course he went a step further, not only faking his operating locations, but also charging the hell out of members of the cult, who by now would pay *anything* to stay on top. My understanding is that he charged $50 per new country for cultists and that this was bringing him a very nice income . . . on the order of over $50,000 a year . . . completely tax free.

I still run into hams in rare spots who remember Miller opening his mail, taking out the money and throwing away everything else . . . piles upon piles of mail. I know that when I wrote my editorial and exposed some of the things he was doing, he sued me for $650,000 for cutting down his income. He sued the League for only $500,000 for besmirching him . . . and lost when it was proven that he had been operating from places other than he claimed. Despite all that, I believe that my cards from Miller are still valid

for awards...and I have a lot of them.

Just as an example, I got a card from him from Burma. Hmmm, I thought that no amateur radio was permitted in Burma. So I went to Burma personally and looked into it. I asked the government about hamming..."no way." I asked the hotel where he said he had stayed and operated from... "impossible." I asked the local amateurs (who had been put off the air and their equipment confiscated)..."totally impossible." When I challenged Miller with this, he changed his story and said that actually he had operated from a hospital instead of the hotel, as he had claimed. Since the hospitals were under army control, not the control of doctors, that obviously was a lie, too. But I wrote back and had that checked out... "false."

If it were a matter of any significance about how many countries any of us has contacted, we might look into ways of trying to stem the cheating. But the importance of this as a goal in life is about on the order of that of the Trobriand Islanders and their fetish of growing pigs with reentrant tusks.

My own experience has shown me that an amateur with a decent station and some operating experience can whack off one hundred countries in one weekend (with the help of a contest). It takes about a month to get 200 worked...and perhaps a year for 300, with some diligence. That's what it took me. Beyond 300 you get into cheatsville and the DXpeditions. That's why I got my 300 and then stopped counting. Now and then I work a new one, but I don't know within 20 countries how many I've really worked...and I don't care.

If the DX awards would stop at 300, it would kill this whole cult and free up a few hundred people around the world to contemplate living more productive lives. We might be able to leave the world of counterfeiting to those who arrange for fake passports and wills.

Speaking of fake papers, I was in Asia one time and found that I had to have an authenticated shot which was not on my health record. A ham in the country fixed that easily. He scribbled in the shot information and stamped it with a checker and stamp pad. Looked great and got me through. I managed not to contract the disease during the visit... perhaps the checker did it.

There are 300 legitimate countries on the air and they are easy enough to contact, so the tendency to cheat might be avoided. It's the last few that bring out the worst in people. Remember that if any one of the Honor Roll chaps misses one new country which comes on the air, he is moved back one rung on the ladder...usually permanently. And that means falling way, way back.

If we could take the pressure off, we might find more DX stations on the air. I've mentioned frequently that when I visit rare spots I invariably find that the operators feel harassed and are not very enthusiastic about hamming. You can't blame them; they are never permitted to get on and rag-chew. They are always haunted by ferocious pileups and demanding DXers who feel it is their right to make a contact of at least ten seconds...and never mind what the operator in the rare country wants to do.

I've heard DXers cursing out ops in rare spots who had given up to go to bed or to work. Well, if you are going to take it all this seriously, then *you* have a problem, not the DX. You are the one who has to decide whether it is worth several days of your time to get a new country. I'll invest up to ten minutes trying for a new one, but that's about the limit for me.

At any rate, getting back to fake cards, it turns out that some of the West Coast gang have gone overboard and have been printing up rare cards wholesale and passing them around. Complaints to the awards people have gone unheeded. There is no question about whether they really care or not. So when one chap brought it to a head by submitting a pile of faked cards all in the same handwriting, *he* was given the shaft and everything else was quickly covered over. At least that is the story going around and, considering the history, it's difficult to find a serious flaw in it.

Even the change to computerized operating isn't going to make a significant difference as far as I can see. I can envision the day when a DXpedition will come on the air from Gherkin Atoll and make contacts automatically at the rate of several thousand a minute, with the logs being transmitted on a second channel as generated to the awards committees of several amateur radio societies. At 9,600 baud, we can pass information through at an effective rate of about 7,500 words per minute without special encoding, so we will be able to get DXpeditions over in a few hours instead of weeks. The QSL manager would also be tuned into the log channel and his computer would print out and send along the QSLs to the QSL bureaus.

But what is to prevent any ham from programming his station to make contacts for everyone in his DX club? Or even to have them check in over a two-meter link and make their contacts? And, if you want to be nasty about it, what is the difference? Any good station anywhere in the world can make contact with a similar station, so all we are measuring with our awards is the amount of time someone is willing to spend for the desired award. There is no real measure of the station, of the ability of the operator, or even of propagation conditions. The awards are, essentially, without any real merit.

So, if you won't get rid of the Honor Roll and its pernicious undermining of our hobby, I'll be pushing forward toward computerized contacts and the day when we can work 350 to 400 countries in a minute or so. Perhaps we will then set up awards for working 400 or 500 countries every day for a year.

Five hundred countries? Sure. That's part of the whole game. The awards groups set up their definitions of countries to suit themselves. No one likes it when he loses a country. The fun is in working ever more of them, so awards committees have to come up with new rationalizations to provide us with more and more. They can whet our appetites by temporarily refusing to accept this or that, generating great and enthusiastic controversy.

Years and years ago, I got together with Bill Orr in Nice and discussed the subject. He came up with a humor article on Countries Galore in '64. Well, most of those enclaves he joked about at the time are now accepted countries. With the SARL accepting Transkei and Bophuthatswana as countries, how long will it take for more of the IARU societies to accept them? Bophuthatswana is a great one, being spread out into a lot of enclaves. We could make that into twenty or more separate countries without even trying. South Africa, in an effort to wiggle its way out of segregation problems, has a lot more similar "homelands" which are being contemplated...each a solid-gold possibility for a new country for us.

Indeed, as I've hinted before, I have my eye on one such territory. As soon as it becomes a separate country politically, I'm planning to rush down there and set up a station and drive you crazy for a few days. I even have a call in mind for it...if this does not give anything away. Of course, we'll have to run it by the ITU first, but I think it is a winner. I've already asked for Q5R9 for my call. Laugh, I hope, but remember that I said it, when you hear me.

Though I am perhaps critical of the DX awards committees for accepting known fraudulent cards, I can understand their problem. With so many of the DXers submitting them, and with it being almost impossible to really know for sure which are the real and which the fakes, it is a no-win situation. But a simple returning of Bob's cards might have been more prudent, rather than making a martyr of him by trying to pillory him for forcing the issue and blowing the whistle.

Keep on accepting the fake cards and shut up. Most of us don't really care.

ZAP! YOU'RE IT!

The September editorial piece about police radar brought in quite a reader response. A lot of you have been zonked by the police, not for actual speeding, but because your transmitter indicated speed on their radar units. You really are going to have to learn from the misery of others and either cut out talking from your car or get a detector so that you know when to shut up.

In case you think that being right cuts any mustard with our court system, forget it. I even have a case of a ham judge who refuses to pay heed to the ham interference defense. Some of us get so wrapped up in our rosy

altruistic imaginations that we forget that the purpose of police radar is not to stop speeding but to make money for towns... and it is a fantastic money-maker. If they say you are guilty, you *are* guilty, and your best bet is to pay up and chalk another one up to our American judicial tax collection system.

Getting down to radar detectors, I've been testing a few more. The newest one is by Fox. It's the smallest one yet and is unobtrusive on the shelf where it can look out of your front window. It's as sensitive as any yet... even matching the famed Escort, which I mentioned in September.

The Super Fox Vixen is about 5" x 3-1/2" x 1-1/4" and comes with a plug for your cigarette lighter socket. Since you have no business smoking any more, this is a fine use for that otherwise wasted socket. On our new Datsun Maxima, where most of the Vixen tests have been run, the power socket is turned on and off by the ignition key, so I don't even have to remember to turn it off when I get out of the car. Most of the radar detectors draw enough current (300 mA) so you will find a dead car battery if you leave 'em on while not using your car for a few days... like at the airport during a trip.

The Vixen, in addition to being small, has the benefit of being distributed through car accessory stores and many electronic stores, so it should be simple to find. The cost is $250, right in there with the Escort ($245).

The only real difference between the Super Fox Vixen and the Escort is that the Vixen has a buzzer and light indicator of radar, while the Escort has those plus an S-meter. Perhaps it is the ham in me that likes to watch the S-meter and see when I am getting close enough to a radar unit to know that it can pick up my ham rig. The Vixen will keep you out of trouble, which is what you want. Be sure that you specify a Super Fox Vixen... the superhet model... as the firm also puts out a Fox, which is a passive detector unit and about 1/100th as sensitive. I have one of those in our RX7 and it generally goes off just as I am passing a radar unit, right at the last minute. Since I have both 2m and CB rigs in the car, if I waited for the passive unit to alert me I would be off the road by now with too many tickets to drive.

I've found that a small square of Velcro™ stuck to the bottom of the unit... and another on my dash shelf... allow it to be whisked off the shelf when I park the car in Boston or at the airport. There's no use dangling a $250 goodie right out there in front of thieves when you can flip it under the seat while parked in high-crime areas. Of course, in New Hampshire this just isn't a problem.

Small world department: The people who handle the promotion and advertising for Fox are the same people who handled DenTron... and are handling OSI, the computer firm. OSI, by the way, was bought by Macom, the firm which makes most of the Gunn oscillators for the superhet radar detectors... and which makes the 10-GHz gear I used for my DXing a year or so ago. Macom, formerly Microwave Associates, is where Sam Harris W1FZJ, the microwave genius, used to work before he moved to Arecibo. The president of Macom is an old-time ham, Dana Atchley.

LETTERS

DAY IN COURT

Thanks very much.

Your September issue of *73* arrived the day after I got an unjustified speeding ticket backed up by police radar. Armed with the information in your editorial, I immediately ordered the legal index and bought an Escort. The delivery of both was very fast and arrived in time to assist my court preparation.

You are too pessimistic. The court is an adversary relationship and the person with the best preparation (among other things) wins. A previously good driving record is also a must. In my case I was stopped for "37 in a 25 mph zone" based on radar. I was sure I was not speeding and so informed the arresting officer. His comment was "tell it to the judge." After obtaining the name of type of radar in use, noting the other traffic immediately before me, etc., and fuming, I read *73*. After obtaining and reading the Fuzzbuster legal index and spending a few more hours in the local law library and in technical reading, I called the Commonwealth's attorney. His initial view was: "Radar is infallible. Some states will listen to technical arguments but not VA."

After the roll was called in court (1½ hours of calling the roll, listening to shoplifter cases, etc.), the court got started on the docket. In a lull, I reminded the Commonwealth's attorney that I intended to plead not guilty and of the technical basis for my defense (RFI from the ham gear causing spurious readings as adequately documented in the manufacturer's handbook, Bureau of Standards tests, etc.). I also mentioned the other traffic in the pattern which was pulling away from me but not stopped. I was supported by diagrams, texts, etc., in a large bundle under my arms. When the case came before the judge, the Commonwealth's attorney recommended dropping the charges.

It took a few hours, but justice is worth the effort. The Escort works like a charm—I won't be surprised again. I may even not key the rig passing the radar next time.

J.D. Peters K1ER
Manassas VA

JD, you're not doing your homework completely. The Car & Driver *article on American justice is necessary reading to dispel your euphoria. Being totally and demonstrably right did not help when the editor of* Car & Driver *lost a clear-cut case ... including two very expensive appeals. When I get complaints from hams in African countries about the sad shape of the courts there, I refer them to the article to show that our courts are not any better... the occasional lucky chap like you notwithstanding.—Wayne.*

SURVIVAL

Your editorial statements and talks concerning the relationship between amateur radio and a productive electronic engineering industry such as that of Japan have intrigued me. I couldn't agree with you more! But I think that there is more to it than is indicated by the numbers of amateurs in a country, or the licensing structure encouraging or discouraging the growth of the hobby. In recent times, the professional literature in science and education has bemoaned what has been happening in our American society and its effect on school curriculum and the courses students take, both in the high schools and in the colleges. (One of the more recent articles for the general public appeared in the *Washington Post* on May 31, 1981, and was written by David G. Savage.) For some years now, many high schools have dropped math and science requirements for graduation. This is also true for many colleges. This is not true in Japan.

The Japanese educational system is rigorous, with mathematics instruction being given in a more concentrated form and with more students taking the advanced courses. By the ninth grade, the Japanese student has had three years of geometry and one year of trigonometry. High school courses include calculus, probability, and statistics. Is it any wonder that (as pointed out in the article by Savage) Japanese leaders often point to the rigor of their educational system as a key to their economic success?

In the United States, about 5% of all bachelors and masters degrees are in engineering. In Japan, about 20% of the bachelors and about 40% of the masters degrees go to engineers. Between 1963 and 1977, productivity in the US grew 39% and 1.6% of our students became engineers. Productivity in Great Britain during this period grew 51% and 1.7% of the British students became engineers. In West Germany, productivity was 114% and about 2.3% of West German students became engineers. In Japan, 4.2% of the students became engineers and

productivity went up 197%. Make what you will of these figures!!

As amateur radio operators, we look to the Japanese for much of our equipment and we are thus familiar with their engineering products and their quality. We hold long and friendly conversations with Japanese amateurs. Russian equipment, on the other hand and for the most part, is unfamiliar to us. The vast bulk of the QSOs between American and Russian hams appears to be a mere exchange of technical information. And nothing could be more deadly to a friendly QSL exchange than PO Box 88, Moscow! Yet their educational system and its productivity is almost awesome to an American educator.

In 1957, the Russians threw a piece of iron called "Sputnik" up into the heavens. America became frightened and began a frantic beefing up of its math and science programs. This lasted until the middle 60s. At that time, while our intense efforts began to go downhill, the Russians decided to go uphill. A recent study by the National Science Foundation indicates that the math and science program required for all Soviet students is far stronger than that of any other nation. Not only do a considerably greater number of Soviet students finish high school (our 75% to their 98%), but their requirements are quite a bit tougher. For example, a high school graduate has had five years of algebra, ten years of geometry, two years of calculus, five years of geography, five years each of biology and physics, and four of chemistry. By contrast in the United States, of the high school graduates, 9% have had one year of physics, 16% one year of chemistry, and 45% one year of biology. Savage points out that each year about five million Soviet high school students graduate with two years of calculus and, in contrast, about 105,000 American students have had one year of calculus.

One might argue that the forced curriculum of the Soviet Union does lead to a resentment of sorts among certain parents and educators, and ought to be tempered. But it might also be argued that lack of a rigorous math and science program in the United States may be at a price much more expensive than the diminution of the hobby of amateur radio. The price being survival.

Marvin D. Solomon WB8VNP
Okemos MI

Thanks, Marvin, for the statistics, which are interesting. Perhaps the lack of interest in science on the part of our students stems from a lack of motivation. If such is the case, if we could spark an interest in amateur radio within our high schools, then we might find our schools more pressed to teach math and science courses. And consider that, if amateur radio had continued its growth pattern from the 50s into the 60s and 70s, that alone would have changed our percentages of students becoming engineers. We're talking about a loss of around 60,000 technicians and engineers per year over the last generation. That magnitude of interest could have had a significant impact on our whole educational system.

If we had continued our growth, I'm sure that amateur radio would be vastly different...more advanced... than it is today. Much of amateur radio is stuck in the 30s, fifty years behind the times. The rest of it is hung up in the 50s, only thirty years behind technically. The amount of progress and experimentation with modern communications techniques is negligible. If I am to judge by ARRL surveys and my mail, most amateurs will fight hard to keep amateur radio from changing. Heck, I still hear AMers on 75m holding forth. Will we continue to be left behind as digital and high-speed communications systems are developed?—Wayne.

TRICKED OUT

We noted with interest the article in the September issue on "Tricking-Out the FT-901/902." It refers to a bandpass tuning feature developed by Bill Orr.

We believe this to be an error, as this feature was first developed by Buddy Alvernaz W6DMA when he was employed by Jennings Radio (now a division of ITT).

There was an article in the May, 1958, issue of *QST* (page 18) which described this feature and listed Buddy Alvernaz as the originator.

WACRAL NETS

WACRAL (the World Association of Christian Radio Amateurs & Listeners—G3NJB) runs the following nets:

- Sunday at 0830 on approximately 3775 kHz, and at 1400 on 7075 kHz;
- Monday at 2100 on 3550 kHz (the CW net);
- Wednesday at 1030 on approximately 3665 kHz;
- Monday and Friday at 1900 on 21,350 kHz (the overseas net).

The purpose of all the nets is to encourage and spread Christian friendship and fellowship—the main aim and purpose of WACRAL itself.

Just as a point of interest, apart from the overseas net, the other nets have been in continuous weekly operation now for over seven years. There is always someone on, and most nets are controlled by me.

ITALIAN LICENSES

We have the pleasure to inform you that on August 28, 1981, a reciprocal operating agreement between Italy and the USA regarding amateur operators was reached.

This department is ready to assist your military or civilian personnel holding a US amateur license to apply for a permit in case of a short visit in Italy or an amateur station license with allocation of an Italian callsign if resident.

Please write for further information.

ROASTED FANNIES

For some time now, Radio Systems Technology has been designing hidden antennas for home-built plastic aircraft using the nonconductive structure of the aircraft to enclose the antenna radiating rod(s).

It has come to our attention that certain builders have been concealing the transponder or DME antennas in close proximity to the pilot or passengers. The usual location of choice has been directly under the passenger or pilot seat structure.

RST would like to point out that this places, in effect, high-powered microwave energy in very close proximity to a rather sensitive part of the pilot/passenger's anatomy. Bluntly, it may be a little like sticking your fanny into a microwave oven.

We are not clinical radiologists, nor do we have the equipment necessary to determine the backscattered field strength of these antennas. We do know, though, that there will be some leakage around any ground plane. Until a competent professional with the necessary training and equipment will volunteer to make the measurements for the rest of the home-building brethren, RST is suggesting that builders who wish to install transponder/DME antennas under the seats also laminate a sheet of plain old aluminum foil into the seat structure to shield the pilot from possible harm. (Microwave energy will not penetrate the thinnest of metallic foils.)

NEW PRODUCTS

LULY POLARIZER

Robert Luly Associates has introduced a new product for the satellite industry, the Luly Polarizer. The Polarizer is an electronic rotator (no moving parts) that replaces the mechanical rotator which was burdened with freezing or burning up, twisting cables, and weight problems.

The Polarizer enables polarity shift from horizontal to vertical automatically. The insertion loss is equal to an N connector, a mere .15 dB. Operating current is 12 to 15 volts at 50 milliamps (available from standard receivers). The polarity can also be varied 0-180°, allowing for dual polarization realignment after moving the antenna from one satellite to the next.

For more information, contact *Robert Luly Associates, PO Box 2311, San Bernardino CA 92405*. Reader Service number 481.

STANDARD COMMUNICATIONS TALKMAN

Talkman is a miniature, lightweight, voice-actuated, hands-free two-way radio; it is ideal for active bicyclists, snow skiers, hunters, and even those engaged in such pursuits as tower rigging and construction. Measuring only 2½" wide, 4½" high, and 3/4" deep, Talkman weighs less than one pound. It is available in any one of five channels in the FM 49-MHz band and will transmit up to a quarter mile. Power is provided with an easily obtainable 9-volt battery. The headset features a stowable whip antenna and an adjustable boom-mounted miniature voice-activated microphone.

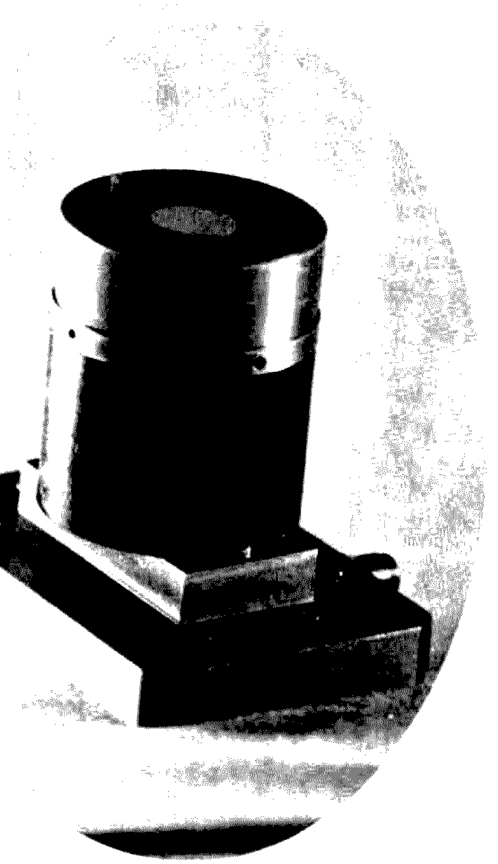
For more information, contact *Standard Communications Corp., PO Box 92151, Los Angeles CA 90009*. Reader Service number 486.

The Talkman from Standard Communications.

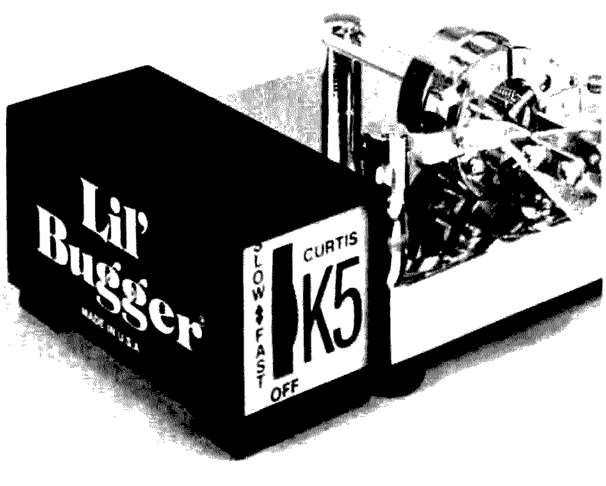
FLEA-SIZE KEYER FROM CURTIS

A rugged, low-priced keyer from Curtis Electro Devices promises to be the tiny, no-frills unit CW buffs have been waiting for. Although only 1.5" square, 3" deep, and 3.5 ounces in weight, the "Lil' Bugger," as it's called, offers many of the features found on full-sized keyers, plus a few of its own. The front panel contains only a thumbwheel speed control. Weighting, sidetone pitch, and volume are adjustable internally via small trimmers. The tungsten output relay will easily key any amateur transmitter, including really tough cases such as old shipboard transmitters. Jacks are provided for the keyline, sidetone output, and an external ac adaptor. The case also contains a compartment for an ordinary 9-V transistor radio battery.

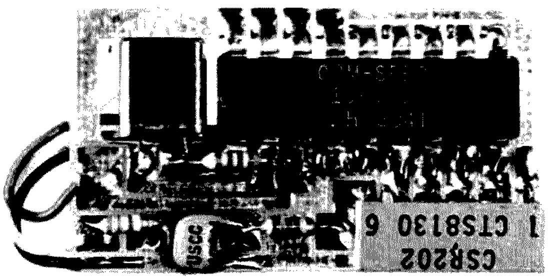
The standard model K5 is equipped with the Curtis 8044 chip. A second version of the unit (model K5B) uses the new Curtis 8044B IC which provides the squeeze-keying characteristics of the Ten-Tec, Heath, Nye, and Accukeyer. In these models, a squeeze released during a dot will automatically produce a following dash. Similarly, a squeeze released during a dash



The Polarizer from Luly.



The Lil' Bugger from Curtis Electro Devices.



Model SS-32M from Communications Specialists.

will produce a following dot. The standard 8044 produces nothing after a squeeze release. Squeeze-key operators are divided into two groups depending on how they learned, so the K5 series accommodates both. Non-squeeze operators can easily use either version.

The small size of the K5 plus the three-lugged leads provided for paddle connection allow the unit to be attached to the side of any standard paddle set with double-sided mounting tape. It is ideal for QRP, Field Day, DXpeditions, or regular station use. Provision for a straight key is also made.

For more information, contact *Curtis Electro Devices, Inc., Box 4090, Mountain View CA 94040.* Reader Service number 489.

TWO NEW VLF CONVERTERS FROM MFJ

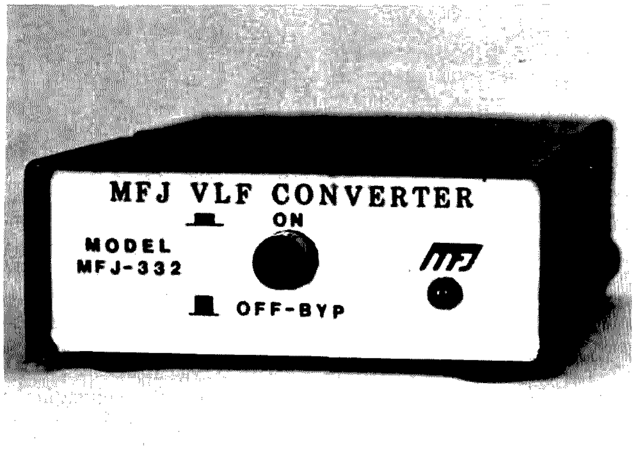
The MFJ-332 VLF converts an HF transceiver into a sensitive Very Low Frequency receiver. It converts 10 to 500 kHz to 28.010 to 28.500 MHz. The MFJ-331 SWL version converts 10 to 500 kHz to 4.010 to 4.500 MHz. Both give direct frequency readout on your receiver.

With a VLF converter, you can *hear WWVB*, ship-to-shore communication, navigation radio beacons, weather broadcasts, and even the standard AM broadcast band (with reduced sensitivity).

Both units easily connect between your transceiver/SWL receiver and antenna. Tuning between 28.010 and 28.500 MHz (4.010 to 4.500 MHz on the MFJ-331 version) lets you receive the longwave band from 10 kHz to 500 kHz. This gives direct frequency readout by ignoring MHz numbers. For example, 28.050 (4.050 MHz) is 50 kHz and 28.375 MHz (4.375 MHz) is 375 kHz.

There is a red LED that indicates "on." The unit is bypassed in the off position for normal operation. The MJF-332/331 VLF converters are housed in black and eggshell-white aluminum cabinets and require 9-18 V dc or 110 V ac with the optional ac adapter.

The MFJ-332 and MFJ-331 are available from *MFJ Enterprises, Inc., PO Box 494, Mississippi State MS 39762.* Reader Service number 482.



MFJ-332 VLF converter.

CTCSS ENCODER FOR ICOM IC-2AT HAND-HELD

Communications Specialists introduces their new SS-32M micro-miniature programmable CTCSS encoder for use in the Icom IC-2AT hand-held. The unit is based on the popular SS-32 encoder and is programmable using jumpers. Measuring just 1.45" x .8" x .13", the SS-32M may also be used in other applications where size is critical.

For more information, contact *Communications Specialists, Inc., 426 West Taft Avenue, Orange CA 92667.* Reader Service number 488.

600 SERIES CES/MICROPAD

Communications Electronics Specialties introduces its new 600 series encoding micropad with DTMF ANI and numerous other features ideal for mobile amateur operations.

"The series 600 micropad," according to CES President Ron Hankins, "is compatible with any transceiver and offers a reliable and convenient design for the mobile radio operator, automatic PTT for 'one-handed' dialing, and ruggedized components."

The micropad incorporates a single-contact tactile keyboard for highest reliability. The series 600 is crystal-controlled and features a quality dynamic cartridge, adjustable tone level, and built-in tone monitor speaker. Noise-free dialing is made possible by a design element which mutes the microphone when the tone pad is in use.

600 series specifications include: 10-15 V dc; 13 mA operating current; −25° to 70° C temperature range; ANI speed of 5 tones/second, and an ANI capacity of 2 codes up to 15 digits each.

For more information on CES encoders and other quality CES products, contact *CES, PO Box 507, Winter Park FL 32790.* Reader Service number 487.

ICOM IC-3A/IC-3AT 220-MHZ HAND-HELD

Icom is very excited to announce a second cousin to the popular IC-2A series—the IC-3AT for coverage of the 220-MHz band. The IC-3AT is essentially identical in appearance, size, and operational features to the popular IC-2A series.

Most importantly, all accessories, including battery packs, chargers, microphone, etc., are completely compatible for the IC-2AT and IC-3A series, so a ham who has already invested in an IC-2A system with accessories can use those same accessories on the IC-3AT.

The IC-3AT also includes a 16-button DTMF pad. It covers the entire 220-MHz band from 220 MHz to 224.99 MHz and is set up for both repeater and simplex operation. The power output is nominally 1.5 W with the standard IC-BP3. The IC-3A system comes complete with IC-BP3 nicad battery pack wall charger, belt clip, rubber duckie, and wrist strap.

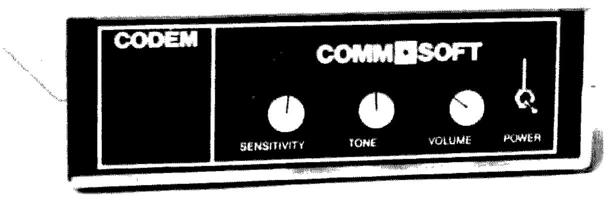
For more information, contact *Icom America, Inc., Suite 307, 3331 Towerwood, Dallas TX 75234.*

COMMSOFT CODEM

The COMMSOFT CODEM, a universal CW interface for personal computers, is now available for radio amateurs. The CODEM provides an easy way to get your Morse code software on the air. Converting received CW audio to RS-232 or TTL signal levels and RS-232 or TTL signal levels to transmitter keying, the CODEM doubles as a code practice oscillator and CW regenerator.

A sharp 800-Hz bandpass filter, AM detector, and low-pass filter are designed into the CODEM to provide outstanding noise and QRM rejection. CW can be monitored using an internal 2" speaker or an external high impedance earphone. Front-panel sensitivity, tone, and volume controls are provided. The CODEM comes with a comprehensive manual which includes operating details and connection instructions. The CODEM requires an external 9 V dc power supply.

For more information, contact *COMMSOFT, 665 Maybell Avenue, Palo Alto CA 94306.* Reader Service number 483.



CW Interface from COMMSOFT.

Model 2020 DMM from Sabtronics.

CODE SOFTWARE PACKAGE FROM COMMSOFT

Hams who own Heath computers can send and receive Morse code with the new CW89 software package from COMMSOFT. The program includes a split screen display, 4-99 wpm operation, receive autotrack, a 1000-character pretype buffer, 10 user-definable messages, unique break-in mode, on-screen system status, disk I/O, hard copy, and a versatile code practice section.

The CW89 program runs on the Heath H-8/H-19, H-89, or Zenith Z-89 computers under HDOS. One disk drive and 32K RAM are required. A hardware interface, such as the COMMSOFT CODEM, is also required. A complete package consisting of CW89, the CODEM, a computer interconnect cable, power supply, complete documentation, and shipping is available. For more information, contact *COMMSOFT, 665 Maybell Avenue, Palo Alto CA 94306.* Reader Service number 480.

REPAIR KITS FOR EIMAC TUBE SOCKETS

Varian Eimac announces PartsKits—emergency repair kits for popular power grid tube sockets used in many broadcast and communications HF/VHF transmitters worldwide.

PartsKits provide replacement items so the user can repair a damaged socket quickly and at a fraction of the cost of a new socket.

Presently available through franchised Varian Eimac distributors are PartsKit-300 for the SK-300/300A sockets, PartsKit-840 for the SK-840 socket, PartsKit-1300 for the SK-1300/1320 sockets, and PartsKit-1500 for the SK-1500/1510 sockets.

For more information, contact Bill Orr, *Varian Eimac, 310 Industrial Way, San Carlos CA 94070.* Reader Service number 485.

DMM FOR MICROPROCESSOR INTERFACING

Sabtronics announces their new model 2020 digital multimeter with microprocessor interfaces to adapt to all the popular home/personal computers.

Combining a high-quality multimeter with a microprocessor interface expands the Sabtronics product line to provide new, cost-effective solutions to data acquisition problems.

The model 2020 DMMM has an impressive 0.1% basic dc accuracy with 3½ digit large LED display for normal bench use. The new DMM is capable of directly measuring ac and dc volts up to 1000 V, Ohms to 20 megohms, and ac and dc current to 10 Amps.

Optical coupling between the DMM and the computer protects the computer from damage and also serves to isolate ground noises that can affect sensitive measurements. The model 2020 DMM will mate with most popular computers.

For more information, contact *Sabtronics International, Inc., 5709 N. 50th St., Tampa FL 33610.* Reader Service number 484.

FCC

BEACON EXPERIMENT AUTHORIZED FOR 10, 18, AND 24 MHz

The Federal Communications Commission has authorized the establishment of an experimental radio beacon on the bands 10.100-10.150, 18.068-18.168, and 24.890-24.990 MHz, these being the bands allocated for amateur radio use by the World Administrative Radio Conference, Geneva, 1979. The experiment is intended to permit amateurs to become familiar with the characteristics of these bands, simplifying the scheduled future changeover to amateur use, to improve amateur use of these new parts of the spectrum, and to provide data on sharing between different services. An important element is securing data on propagation under weak signal conditions, typical of natural disaster situations. It will be recalled that this use is one of the major reasons for these new authorizations, the first in many years.

The experiments will include two emission types, three operating modes, and two time phases. Basic emission is unmodulated carrier (A0), interrupted each ten minutes for an SSB (2.8A3J) identification and announcement, this occurring at 2, 12, 22, 32, 42, and 52 minutes past the hour. Announcement will be of the form: "This is FCC authorized experimental station KK2XJM, Daytona Beach, Florida. QSL via W4MB. Next operation will be repeated on ______ MHz starting on ______," and will be repeated.

Initial operations will be at 3 Watts ERP, on 10 MHz, commencing about the first of October. In stages, the schedule depending on results, operation will include 18 and 24 MHz. Later phases will include operation at 30 Watts ERP, with sequencing from band to band, sometimes weekly, sometimes daily, as

needed to make optimum use of the bands for propagation experiments, worldwide and to specific areas.

Licensee for the experiment is Robert P. Haviland, amateur call W4MB. The success of the experiment depends on participation by amateurs and SW listeners, and on their reports. Information needed is date, time, and location of reception, strength of signal and of other signals on the band, and nature of the receiving installation. All reports will be acknowledged by QSL.

In addition to reception reports, proposals for special tests will be welcomed, subject to the limitations imposed by the license and by regulations for experimental stations. At this time, there is no authorization for communication with amateur stations.

Reports, requests for schedules, and proposals for experiments may be sent to W4MB at the *Callbook* address, or to R.P. Haviland, 2100 South Nova Road, Box 45, Daytona Beach FL 32019.

ID RULE CHANGES

On October 1, the FCC announced a change to 97.84, the rule dealing with identification of an amateur station. Section (a) of 97.84 has been changed to read:

"Each amateur radio station shall give its callsign at the end of each communication, and every ten minutes during a communication."

The change deletes the requirement for giving the callsign of the other station at the end of the contact. However, *both callsigns must be given at the close of any communication involving international third-party traffic.*

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randalistown MD 21133

The original Wahl cordless clipper.

Let me take a look outside, at December in Maryland. Hmm. . . "The weather outside is freezing, and the RTTY machine is teasing. So since you've got nothing to do, call CQ, call CQ, call CQ!" Here we are again, with the holiday season fast approaching. Last year, I described several gift suggestions designed to gladden the heart of any RTTYer. By your response, I see that this outing was well appreciated. Let's do it again right now.

I'm going to start by telling a story. Once upon a time, oh, say about 1968, a company out in Sterling, Illinois, introduced a cordless hair trimmer to the barbers and beauticians. Featuring a nifty little case which housed a nickel-cadmium battery, it dropped into a stand into which a charger was built. Convenient, portable, and well designed, the clipper was an immediate success in the industry.

The company then decided to look around to see what other uses this little dynamo could be put to. Not having any preconceived notions, the engineers added a resistive element across the battery and came up with a cordless rechargeable soldering iron. Not only the company's own marketing people, but also many others greeted this new device with less than total enthusiasm.

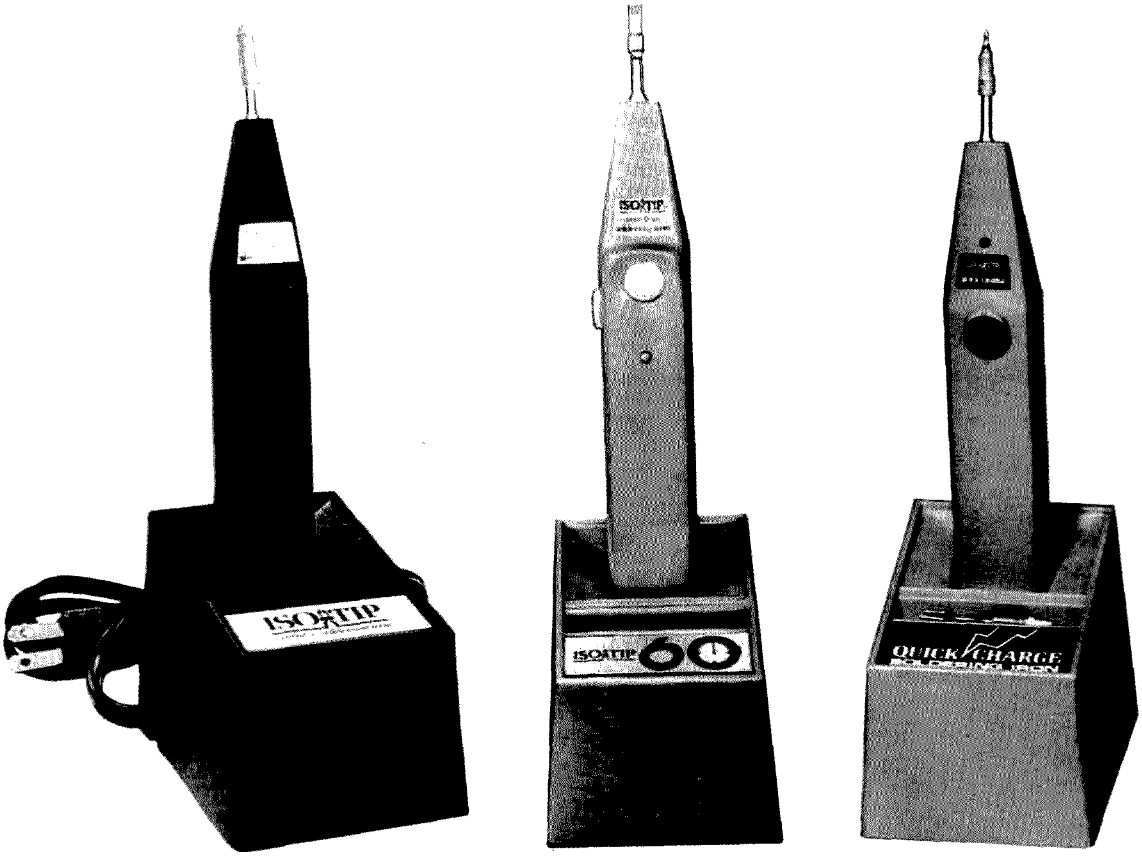
Nonetheless, in late 1971, the Wahl Iso-Tip cordless soldering iron was introduced. By mid-1972, the product began to trickle down to consumers and we hams became the biggest boosters. For working on printed circuit boards, especially with static-sensitive components, the Iso-Tip is hard to beat. Because it is not connecting to the line, the possibility of passing through a charge is minimized. Sitting in its charger, the iron is always ready, reaching soldering heat within seconds. My iron quickly became one of the most used tools in the shack, whether for revising a circuit board, fixing a plug, or using the built-in light to illuminate the recesses of a piece of equipment.

Since that time, the R & D boys at Wahl have not stood still. The original iron took 12 to 16 hours to fully charge. This is fine if all you are going to do is an occasional job or two. The capacity of the iron, fully charged, is about 125 solder joints. So, if you have to hot-wire a board or fix a chip, all is well and good. But there is no way to build something complex, without stopping after an hour or so for recharging. A "quick-charge" model was then introduced, which charged to capacity in three to four and one-half hours. By dropping the iron into the recharger between joints, larger jobs became more practical. The latest development along these lines came in 1977, when the "Iso-Tip 60" was introduced. This one will charge in only one hour, enough to keep anyone happy.

Continuing the search for innovative uses for that nickel-cadmium battery, other items have been added to the line. A nifty little drill is available that slips over the top of any of the soldering irons. The drill holds a fine bit ideal for drilling out holes in printed circuit boards. Automobile battery charger cords and various soldering tips and bits round out the portable line.

That nice little drill, by the way, is also produced in a self-contained version, powered either by a transformer from the ac mains or an automobile battery. Another fine addition to the line.

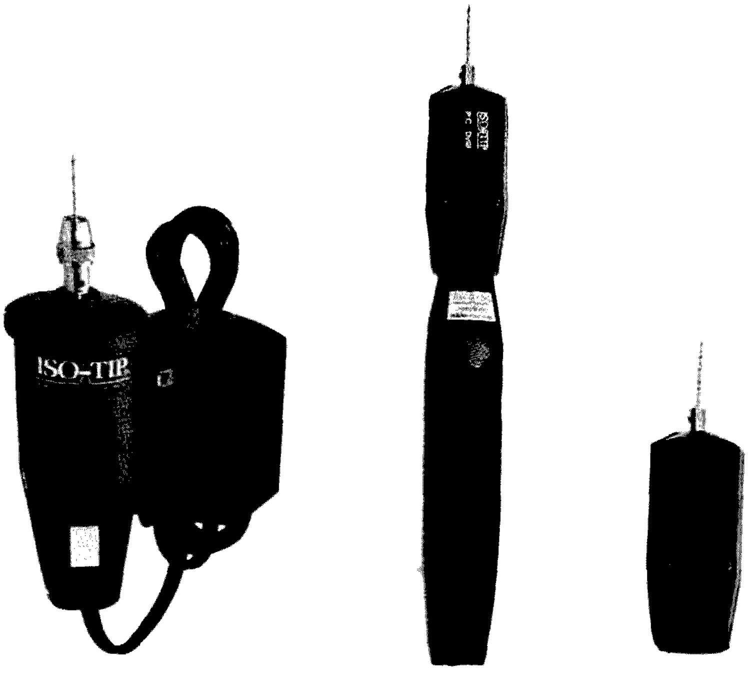
When looking for a gift idea to satisfy the ham involved in RTTY



The Wahl Iso-Tip line.

or computers, this line may just turn the trick. Prices range from a few dollars for a soldering tip to under thirty dollars for the basic iron with drop-in charger. The quick-charge iron is about five dollars more, and the drill attachment about twelve. Look for them at your local dealer, or write to the Wahl Clipper Corporation, 2902 Locust Street, Sterling IL 61081. Be sure to tell them you read about the Iso-Tip here, in *73 Magazine*'s RTTY Loop.

In the market for something a bit more, shall we say, meaty? How does this strike you: a hard-limiting FSK demodulator, capable of handling 170-, 425-, and 850-Hz shifts; of interfacing with 20-mA or 60-mA loops *or* RS-232 *or* TTL-level logic; with autostart and built-in tone keying; all in a case two-thirds the size of this page and costing under $250? Well, it strikes me just fine, and I call it (or more properly IRL calls it) the FSK-500. This demodulator looks like the way to go for the ham looking for a compact but effective unit for a modern RTTY station. Next month I will



The Wahl printed circuit drill.

go over this beasty in detail, but if you want to pick one up now, I am sure that the folks at iRL would be happy to oblige. Drop them a note at iRL, 700 Taylor Road, Columbus OH 43230. Don't forget to plug RTTY Loop, OK?

Now, let's look at a new RTTY activity. The Chicago Area RTTY Repeater Society (CARRS) has announced its first RTTY Art Contest. Running from November 1, 1981, through February 28, 1982, the contest seeks new RTTY art. All entries must be original to licensed radio amateurs and their immediate families and must not have been transmitted before November 1, 1981. Entrants must supply one unspliced five-level tape and three prints for each entry submitted. Format specifics include no limit on running time and a maximum of 72 characters per line. Entries must be compatible with machines running "downshift-on-space." Each line should be terminated with a minimum of three functions: CR-LF-LTRS sequence. Entrants agree that the submitted picture(s) may be used, duplicated, and published for any purpose by CARRS.

Judging will be by the CARRS Board of Directors and will be based on originality and technique. The winning entry will earn the winner a reconditioned Teletype® ASR-33 complete with modem, FOB Chicago. Send entries to Howie WA9KEK, 1752 North Austin Avenue, Chicago IL 60639.

As I mentioned a few paragraphs ago, the FSK-500 will be on tap for next month. Never one for organization, I might just scrape up another item or two—you'll have to wait and see. You never know what might turn up here, in RTTY Loop.

CORRECTIONS

Several readers have pointed out a potential problem using my program for transmitting and receiving Morse code with the TRS-80 Level I, appearing in the September issue ("TRS-80: Your Electronic Brasspounder").

If the program is to be used only for transmitting code from the keyboard without first connecting the 1NS8255 interface represented in Fig. 10 (page 94), the program will lock up within the downtime loop between memory locations 4607h and 4614h of Fig. 3 (page 91). This problem may be solved by substituting a JP TX statement for the CALL SKEY statement appearing at memory location 4583H. The resulting line would then appear as:

```
4583   C34047   JP TX
;Jump around SKEY
```

If at a later date you wish to utilize the receive program, the statement may be reinserted without any difficulty.

I have failed to provide the pin connection of pin 6 of the 1NS8255. This pin is the chip select, and for my purpose I have tied it to pin 7, making the chip always selected.

There have been inquiries as to whether I have modified the program for Level II. The modified program has the following improvements made to it:

- The buffer space is cleared to prevent a garbage, end of buffer, flag from being inserted.
- The video screen is cleared on program entry.
- Return to BASIC is allowed from the program.
- The operator is given a prompt for message entry.
- Program is written in Assembly language using Radio Shack's Editor/Assembler.

Anyone interested in obtaining a source listing may write to me.

Donald C. Downs N0AGX
1705 S. 5 Street
Marshalltown IA 50158

OSCAR ORBITS

SATELLITE NEWS

UoSAT-OSCAR 9 Launched

Satellite enthusiasts now have another "amateur" bird to chase. UoSAT, a British satellite that combines research and amateur applications, was successfully launched early on the morning of October 6. Listeners were able to copy a signal from UoSAT's two-meter beacon, starting with the first orbit. Once aloft, the satellite was dubbed the "UoSAT-OSCAR 9 spacecraft."

UoSAT is not a communications satellite but it will be transmitting on a variety of amateur frequencies. For a more complete description of the satellite's capabilities, which include slow-scan television, see "Phase III and Beyond" on page 96 of the September, 1981, issue of *73*.

OSCAR 8 Still Flying High

Despite the demise of OSCAR 7, hams are still communicating via satellite. Recent accomplishments made via the OSCAR 8 satellite include the first mode J Worked All States Award which is credited to WA6GVS. Following on his heels, W7UFE completed mode J W.A.S. In doing so, he has become the first person to accomplish W.A.S. on each of the satellite modes, A, B, and J.

The DX scene was busy, too, with a record-setting mode J QSO between W4AUZ and GM4IHJ. Details about tracking OSCAR 8 can be found in the November issue of *73*.

Phase III Looking Good

Plans are being made for the launch of Phase IIIB, a replacement for the ill-fated original Phase III satellite. The third test of the Ariane rocket was a success, representing a tremendous breakthrough after Ariane's failure on May 23, 1980. AMSAT officials are preparing for a Phase IIIB launch in the fall of 1982. For more details about the Phase III program and other aspects of the amateur satellite service, contact AMSAT, PO Box 27, Washington DC 20044.

An error crept into the calculation of the OSCAR orbits published in the October and November issues of *73*. As a result, the equatorial crossing times are incorrect. Hopefully, the December predictions represent a great improvement in accuracy.

HAM HELP

I would greatly appreciate any information (schematics, service manuals, performance improvement, etc.) on the following equipment:

a) Clegg Thor 6 transceiver;
b) Simpson Model T marine transceiver;
c) Konel Gemini III marine transceiver;
d) Johnson Ultracom 30-50-MHz FM transceiver;
e) Lafayette PB-50 30-50-MHz FM receiver.

I will copy and return manuals and refund postage costs. Thank you.

Gary B. Trustle WB8SPV
424 Franklin Ave.
Waverly OH 45690

Help, help! We have a Telrex beam, Model TBS-308, and need any information available on assembly details to permit correct operation on certain frequencies. It is a tri-band beam, traps *and all*, apparently two elements on each band. Any data would certainly be appreciated. Telrex Labs does not have data on this old a beam. I will cover any duplication costs if required and postage. Thanks for any help.

Paul Wiegert W8TH
1205 E. Franklin Street
Centerville OH 45459

I need manuals/schematics for the following units: EICO 752 dc power supply, Standard Communications SR-C803L VHF FM transceiver, Triplett 3434 TV-FM sweep/marker generator, and Clegg HT-146 2-meter handie-talkie.

I would prefer to buy, or copy and *return your* original, especially on the HT-146 as Clegg does not have an original. And does anyone have a battery for the Clegg?

John E. Carter WB4HLZ

TR-7730 *from page 27*

doesn't help matters much, but under most daylight conditions, the display is pretty hard to read. The other two problems I encountered involve the scanning circuit. There are an awful lot of 5-kHz split repeaters out there now, and it would be useful if the band-scanning circuitry stopped with the discriminator centered. There are currently only two rigs available that offer this feature (that I am aware of)—the Azden and the KDK 2025. Finally, for some reason the rig scans much slower in the memory-scanning mode than in the band-scanning mode. It should be easy to speed up the scan rate; the first person to come up with a good mod is guaranteed an article in *73!*

These last two points are purely personal opinion, and others may never complain. The dim display is another matter and has plagued almost every two-meter rig I have used. It's time for the industry to correct this problem. I'd like to see a blue display like the one on the TS-830S, with a dim switch for nighttime driving. I realize that it would be expensive, but the ultimate solution might be a light-sensing circuit like the one found on the IC-701.

Conclusions

Simply stated, the Kenwood TR-7730 is one of the best two-meter FM rigs for mobile operation I have used. I have used rigs that offered more features, rigs with better receivers, and rigs with brighter displays, but I have yet to test anything that combines the features, performance, compact size, and reasonable price of the TR-7730. For home use I might prefer something with more memories, like the new KDK, the TR-7850, or the Azden. For installation in the small cars that Americans are wont to buy, the TR-7730 is sublime.

KAHANER REPORT

Larry Kahaner WB2NEL
PO Box 39103
Washington DC 20016

CORRECTION

For those of you who wrote to me about my column on competition for AT&T in the local and long-distance market (Oct., 81), I noticed the error also. Seven digits comprise a local phone number, not five as mentioned.

STALKING THE WILD BUCK

The buck never stops anywhere in Washington. It just kind of makes the rounds.

The FCC complains it lacks the power to do its job. It says the Communications Act of 1934 is too out of date to allow the Commission the legal leeway it needs to cope with our new technological age. The Act never envisioned millions of private radio users, large numbers of radio and TV sets, and an era where information would be a money-making, fast-trading commodity like rice and wheat.

According to the FCC, the Act doesn't give it permission to pull licenses of violators—they must trek through lengthy court proceedings—or set minimum standards for receivers making them less susceptible to interference.

Congress, on the other hand, has tried to rewrite the Act every session for the last 10 years, but so far has only succeeded in tacking on some satellite amendments in the early 1960s. In addition, Congress complains that the FCC doesn't use the powers it does have under the Act and is afraid to flex its muscles fearing some court will overturn the administrative decisions. The bickering is boring.

During the peak CB surge of 1977, the Commission logged more than 110,000 interference complaints. About 85% were traced to CBers overloading nearby TVs or assaulting them with harmonic radiation. Since then, the average number of complaints has never dipped below 80,000 per year. And that's half the actual count; the FCC estimates that that figure represents less than half of interference incidents.

Again the FCC laments that it doesn't have the legal right to set minimum standards for TVs. Congress doesn't amend the Act, so nothing happens at all.

But although the FCC supposedly wants that power, and some others, it's not helping Congress to rectify the situation.

In 1978, the FCC launched an inquiry into interference. It was to be the final word on the subject. Part of the reason for the investigation was to present Congress with facts about interference so when the time came for it to tackle the problem, the lawmakers would be well prepared.

The unfinished 3-year-old report, broached at a recent FCC meeting, stated: "Minimum standards for receiving equipment might be necessary." It offered no details, no technical standards.

FCC commissioner James Quello angrily referred to the sparse report during the June 17 meeting and said: "There hasn't been any movement since 1978, and the interference is getting worse. How many more years do we need?"

The Commission wanted to present the report to Congress in response to several recurring bills to regulate TV susceptibility to interference. Congress asked for FCC comments and guidance and this report was supposed to supply it. Said Quello: "And what do we tell them [Congress]?"

Commissioner Anne Jones responded sadly: "Let's start with an apology."

Even though the FCC is supposed to know more about communications than any other governmental agency, their input to Congress in this case appeared minimal.

This year, Congress seems closer to revamping the Communications Act than during any other session. Although most of the bill—commonly referred to as the Domestic Telecommunications Act of 1981 (S-898)—deals with common carrier and broadcast matters, some provisions affect hams, CBers, and other private radio licensees.

Now that the bill heads for the Senate floor, the FCC has jumped up and put in its 2 cents worth. If the FCC suggested any courses for Congress to follow during the writing, the lawmakers certainly didn't pay that much attention. Some FCC suggestions—called amendments—deal with semantics, others with substance.

Without going into the bill's details, here are some FCC amendments submitted to Congress:

- Give the FCC permission to employ volunteer amateur radio operators to administer tests to those seeking licenses of equal or lower rank.
- Allow use of volunteer hams and CBers to monitor airwaves for violations.
- Permit aliens to obtain operator licenses.
- Allow elimination of CB licenses.
- Allow suspension of licenses of those who aid and abet violators.
- Allow the FCC to issue cease and desist orders in cases of safety.

The FCC proposes many other items, but these most directly impact hams and CBers.

You might know that the FCC doesn't need Congressional mandate to permit volunteer license proctors. General class license holders and above now administer tests to Novice hopefuls. Nor does the FCC need permission to allow aliens to hold licenses. It does that now in some cases.

So, why bother? For one thing, a bill reassures the FCC that it really has all that power. Secondly, the Act ties it all up into one neat bundle, and the FCC doesn't have to take it upon

LATEST RECIPROCAL LICENSING AGREEMENTS

Hare's an updated reciprocal licensing/operating list:

Argentina	Italy
Australia	Jamaica
Austria	Jordan
Bahamas	Kiribati
Barbados	Kuwait
Belgium	Liberia
Bolivia	Luxembourg
Botswana	Monaco
Brazil	Netherlands
Canada	Netherlands Ant.
Chile	New Zealand
Colombia	Nicaragua
Costa Rica	Norway
Denmark	Panama
Dominican Rep.	Paraguay
Ecuador	Peru
El Salvador	Philippines
Fiji	Portugal
Finland	St. Lucia
France	Seychelles
West Germany	Sierra Leone
Greece	Solomon Islands
Grenada	Spain
Guatemala	Surinam
Guyana	Sweden
Haiti	Switzerland
Honduras	Trinidad & Tobago
Iceland	Tuvalu
India	United Kingdom
Indonesia	Uruguay
Ireland	Venezuela
Israel	Yugoslavia

LATEST THIRD-PARTY AGREEMENTS

The FCC issued an updated third-party list:

Argentina	Haiti
Bolivia	Honduras
Brazil	Israel
Chile	Jamaica
Colombia	Jordan
Costa Rica	Liberia
Cuba	Mexico
Dominican Rep.	Nicaragua
Ecuador	Panama
El Salvador	Paraguay
Gambia	Peru
Ghana	Trinidad & Tobago
Guatemala	Uruguay
Guyana	Venezuela

Also, ITU headquarters in Geneva, station 4U1ITU

itself, administratively, to change any regulations.

No one knows if the bill will pass, even though it seems well on its way. However, if it speeds towards the president for his signature, there's no guarantee that Congress will slow down and consider the FCC proposals.

At presstime, the Senate unanimously passed bill S-929 which gives the FCC absolute authority to set minimum standards for TV sets and other receiving equipment. Titled Amateur Radio Service and Private Land Mobile Services Act of 1981, the bill won't apply to existing equipment.

Other sections: License terms raised from 5 to 10 years, hams and CBers permitted to monitor the airwaves in their own services for violators, and hams may administer licensing tests.

The bill passed the Senate only after it added an amendment giving the FCC permission to eliminate CB licenses.

FCC chairman Mark Fowler lobbied for and received the last concession. He wants the Commission out of the CB licensing business and claims the move will save the FCC more than $½ million a year.

No one is sure if that bill will pass either.

Note the wording in each bill. Each gives the FCC permission to do all these new things, but doesn't force it to do so.

Perhaps it doesn't even matter. Each side has excellent excuses for not doing anything and neither wants to jeopardize that safe position. Make no decisions, make no enemies.

And the buck just keeps on passing.

A CHRISTMAS PRESENT: SANTA BARBARA'S SUCCESSFUL REPEATER

We begin this year's Christmas special with a true success story, the story of a two-meter repeater located near the city of Santa Barbara, California. What puts this system a cut above the rest? Think in terms of other stories you have read in this column—stories depicting the rise and fall of other repeater systems. Also remember that the 2-meter FM scene in southern California has never been very stable. Rather, it's factionalized. Where else in the nation are 146.34/.94 and 146.16/.76 still simplex channels for the most part? Yet the WR6ANW repeater has survived and prospered. Not because it's away from Los Angeles proper, but rather because things were done right to start with. Here is the story as told by Jay Hennigan WB6RDV in the June, 1981, issue of *Key-Klix*, the monthly newsletter of the Santa Barbara Amateur Radio Club.

A HISTORY OF K6TZ/R

A Gift from Delco

The SBARC 2-meter repeater had its humble beginnings as a portion of a gift of surplus Motorola radio equipment donated by Delco Electronics. The equipment consisted of two 150-MHz dish antennas. All of the above was immediately scattered throughout the county, with the majority winding up in the garage of WA6OOO on Palisades Drive. This arrangement made it rather difficult for Darryl to put cars in his garage, considering that a certain individual had a Progress-Line autopatch and a jukebox or two stashed there as well. The dishes, and a lot of the less-immediately-usable gear, wound up in the backyard of Sonatech, Inc., work QTH of WB6RDV, WA6OQZ, and WA6LWJ.

Where to Put It?

Obviously, such a generous gift was destined to become a 2-meter repeater. The only remaining questions were at what location and on what frequency. Several physical locations were scouted out, with the final location picked as the city radio site on Lavigia Hill on the Mesa. One thing the city required was a statement by a licensed civil engineer that our tower, identical to several other towers installed by the city at the same location, would not fall down. This survey was provided free of charge by Dave Harris, father of KA6OFZ. The next question was one of frequency. Some people within the club felt that our repeater should be on a "common pair" such as 146.34/.94 or .16/.76. In those days, 99-plus percent of amateur 2-meter gear was crystal-controlled, which resulted in a conflict between having the repeater on one of these "common" frequencies, making it available to most amateurs passing through town, and the refusal of several hundred southern California FM pioneers to give up .94 and .76 as simplex frequencies. The club looked into several other pairs and eventually a tape recorder was installed at the site to listen to two different frequencies as possibilities (146.19 and 146.22). The selec-

tion was 146.19, having the least co-channel interference, and a sanction was received from the Southern California Repeater Association for its use. The club now had a location and a frequency. All that was needed was some personpower and a license.

A Taste of Root Bear

In the good old days, licensing a repeater was about as much of an ordeal as licensing a nuclear power plant is today. The FCC required numerous drawings, sketches, schematics, and calculations, and it seemed as if they were sadly lacking in the people needed to review and process all of this material. A thick packet was sent to Washington by the club's technical committee, and as we waited we were not idle. The duplexer, antenna, and tower were ordered and received, along with some 75-Ohm hardline, which was definitely *not* ordered. A call to the manufacturer revealed that it was their goof. UPS and the post office refused to carry the stuff back to LA for exchange, although it would and did fit in the back of a VW. Winnie, now KA6OFZ, ran it down to LA for exchange. After what seemed like an eternity with no word from the FCC, K6YX, our then-trustee, called on them in Washington (in person) and was informed that the license had been processed with a call of WR6ANW. The identifier was programmed and the repeater was tested. When the license arrived in the mail, it had the call of WR6ANW and the root-beer box was born.

Out of Control

Although we now had a working repeater, there was no way to control it. The club had installed a telephone line at the site for a dial-up control system, but no such control system had been built. The trustee stated that if there was no control system by January of 1977, the repeater would go off the air. WB6RDV and company worked feverishly on New Year's Eve and came up with a dial-up control system. No tone decoders were available at the time, so the control codes consisted of dialing an unlisted phone number. One call would turn the repeater off and the next call would turn it back on. Every so often, the repeater would mysteriously go off the air due to someone dialing a wrong number. This "temporary" control system was upgraded with the addition of some touchtone™ decoders to give a more positive on-and-off command, and was to be replaced when the new cactus-style control system was completed. Parts were ordered and meetings held with Alan Burgstahler WA6AWD, who agreed to sell us blank PC boards and plans to build the sophisticated control system that we have today.

The boards were farmed out to many club members for drilling and stuffing with parts. The temporary control system, it seemed, was going to be rather permanent as progress on completion of the new control system was exceedingly slow. A new receiver was donated by Dean Dods WB6IYW and installed to cure several problems which were developing with the old tube-type receiver. It became evident that the newness was wearing off and several corrective maintenance items were necessary. Our new antenna was taken down for repairs and the duplexer had one cavity go bad (which was sent back to the manufacturer). In addition, the city was in the process of expanding their building right over the area where the repeater was located. A work party retrenched the antenna cable and the repeater was moved to a wooden pallet about 10 feet from its former location. The electric power and telephone line were brought out by extension cords draped through the bushes, and the "temporary" control system was still in operation some three years later.

The Housing Crunch

It became obvious that some sort of permanent structure would be necessary to enclose the repeater. SBARC went to tremendous effort to build a very rugged plywood box large enough to enclose the repeater and duplexer. The box was delivered to Valley Telecom, Inc., the new business of WB6RDV, and it is still there. In the interim, the city had agreed to provide a separate building for the SBARC repeater. At some time during this period, the WR6ANW callsign expired and the new club call of K6TZ/R was programmed into the repeater.

The New Machine

As time took its toll on the older equipment and more frequent repair trips became necessary, it became obvious that the good old root-beer box might not stand up during an emergency. In addition, the club wanted features such as autopatch. A grassroots fund raising was spearheaded by WB6OBB and N6CPN and the club ordered a new all-solid-state GE repeater. The pace picked up on completion of the cactus control system. The new machine arrived and was installed in its new house, originally without the new control system. FCC rules had relaxed, allowing automatic repeater control, and the temporary control system was laid to rest along with the original repeater. The cactus control system, finally complete, was installed along with a 440-MHz control receiver and temporary autopatch on loan from W6YJO. The new control system functioned well for a time but was damaged by a nearby lightning strike during a storm. We are currently operating under automatic control once again.

The Future

Most of the problems with the control system have been repaired and a new, more sophisticated autopatch is in the design stage. The repeater now has full battery standby power as well as standby ac power provided by the city generator. The new control system is expandable to fulfill future needs, and the basic repeater has proved to be a very reliable machine. The SBARC repeater fund is still attempting to recover from the purchase of the new machine, and future improvements will be made as funds become available.

CHRISTMAS IN THE CITY OF THE ANGELS

I guess you all know that this is a special time of year. Even here in Los Angeles, most of the major thoroughfares are alive with holiday decorations and the spirit of the season is in the air. Also, on the air. Shortly, it will be time for "Operation Santa Claus 1981," in which amateurs from all over the area take their portables and hand-helds into local hospitals so that children confined in those institutions can get their chance to communicate with Jolly Old St. Nick.

We have written about this topic before. We told you how it was started more than 20 years ago on the old Mt. Wilson WA6TDD repeater by W6AOP and K6SJJ, among others, and how this event has withstood all forms of adversity over the years, including some organized jamming in recent times. No matter what, "Operation Santa Claus" will happen. It's become as important a Los Angeles area tradition as the decorations along Wilshire Boulevard. It will happen again this year, and it will succeed again this year.

Most hams belong to one or more radio clubs in their area. I wonder how many of you have ever thought of undertaking a project like "Operation Santa Claus," but failed to bring the idea to the attention of the rest of the members. True, it's a lot of work. You can't expect to start on Sunday with planning and be ready to roll the following Wednesday night. The logistics of this kind of operation are such that very careful consideration must be given to every detail. The obvious first step is to make contact with the hospitals in your area and simply offer the concept. Since this might be a bit of a job in itself, do give yourself ample lead time. Right now is a good time to plan for next year. The hardest part will be reaching the proper official with the power to make a decision. You may have to work through an intermediary, but if you've got the tenacity and can be convincing enough, you will probably get the green light. A good argument in favor of the project is the longevity of the Los Angeles area operation.

Next, you must select your operating mode. Here VHF and FM are naturals. This is because of the lightweight portability of equipment and the fact that no connection to power mains is needed. Avoid hand-helds unless they are equipped with external speaker-microphones. Many of the kids you will visit may not be ambulatory. As you know, using a hand-held while lying flat on your back is not the easiest thing to accomplish even for the trained operator. Now think of trying to be station in control for an invalid child who has never before seen a hand-held. If you don't have a speaker-mike for your rig, you might pluck that old TR-22 out of the closet and blow off the cobwebs. Radios like the TR-22, TR-33, and TR-2200 are best for this type of operation.

It's also necessary to avoid massive equipment installations which require outdoor antennas and connections to the ac power mains. If your particular site dictates that you must operate from a fixed location using ac power, be sure that all equipment is grounded properly using 3-wire line cords. Do not try to cheat the system with adapters and the like. Besides the fact that most hospitals will not permit this in the first place for safety reasons, you run the risk of personal liability if someone should be injured as the result of your negligence. Remember: You may be performing a public service, but you are still someone else's guest and you live by their rules.

What about Santa Claus himself and his North Pole home? Where should he be located? You play this one by ear. In Los Angeles, a large number of hospitals are visited every year. It would be all but impossible for Sid McCormack W6BWC, who is our Santa, to visit each. Sid operates from a centralized North Pole and communicates over a system of intertied repeaters to hospitals as far to the east as Riverside, to the west to the ocean, and to the south half the distance to San Diego. The logistics of the LA Operation San-

ta Claus seem to grow each year, but each independent geographic area and involved club will have to decide what's best for itself.

For example, if you can only visit one hospital, Santa can be on site. That is either in a vacant room, in his mobile, or anywhere near enough for full-quieting simplex operation. It's lunacy to tie up a busy repeater for an evening if Santa and his flock are within a few yards of one another. Also, avoid unintentional interference from outside. Stay off .52 or any other heavily used simplex frequency in your area. Choose some oddball away from the mainstream of 2-meter activity. True, you will lose your outside audience, but you will also avoid problems from outside your operation.

On the other hand, if logistics dictate the use of a repeater, possibly because your operation is quite large in nature, then try to find one that has a low utilization factor. While you might find this hard to believe, there are some hams who will object to having their favorite rag-chew session interrupted for any reason. These are the people who ratchet-mouth through tornado and hurricane alerts; unfortunately, we have our share of these un-public-spirited individuals among us. If you have no alternative but to use a specific system, then be sure to publicize the event well in advance. Make sure every member of the club knows that the repeater will be closed to all but the Santa Claus operation and emergencies during a specific time period. List the operating schedule in your newsletter and have someone make periodic announcements at least two weeks prior to the event. Make sure that hams from other repeaters and clubs know as well. Not only may you pick up some needed extra help, but you will also avoid hurting anyone's feelings the day of the operation when all on the frequency must be requested to vacate. Prepublication of your operating schedule will give all a chance to find alternate places to operate.

If your area is plagued with malicious interference—if the sick minds are out there just waiting to give some poor sick child a deluge of four-letter atrocities—then do not even consider the use of a repeater. Even a private tone-access system. Better you have a Santa on the run from hospital to hospital than demean the operation by letting some half-crazed jerk spoil the fun for the kids in order to get his own kicks. If the distance between locations makes having a Santa on the run an impossible task, then you might consider borrowing someone's remote base for operation from "Santa Central" to the field units. The very nature of a remote base, i.e., simplex channel operation, tends to minimize the kook factor. Also, even with a remote base, stay on some uninhabited simplex channel. Most potential jammers are not all that astute. Very few will go out and purchase a 220-MHz or 450-MHz synthesized radio in hope of locating your control channel just to cause you misery. Even so, be prepared for any eventuality, for any troublemaker who might come along. Some people no longer believe in Santa Claus. Some of these object to you or anyone else believing either. Need I say more?

What about your Santa? First of all, he should have the kind of voice and personality that kids already associate with St. Nick: warm, friendly, and understanding. It will probably be hard to choose from among the many volunteers for the position. Who wouldn't want to be "Santa for a Day"?

Since Santa is supposed to be live and direct from the North Pole, some North Pole sound effects might be in order. Nothing elaborate... and nothing you can't get from a Christmas sound effects record from your local five and ten cents store. Transfer the sounds you need onto endless loop cassettes and put the player within range of your mike. Adjust the volume to where the background on another radio seems real and there you have it—instant North Pole. Loop cassettes or, if you prefer, endless loop cartridge tapes, will keep you from having to rewind tape at an inopportune time. Make a few different tapes or carts. If you have the equipment, you might want to edit and re-mix sounds for greater realism. You might even approach a local radio station for help on this, which could bring a side benefit of news coverage as well. A bit of good public relations for our hobby never hurts. Also, in relation to publicizing your event to the general public, I suggest you read "Free PR for Ham Radio" in the September, 1981, issue of *73*. Rob Diefenbach WD4NEK has been very successful in this department and his article shares his secrets with you.

One note from someone in the business. If you make arrangements for TV coverage, keep that schedule to the second. Television news is a split-second industry and it's very easy to get an assignment editor irate by having his crew show up to find nobody ready or the event completed. Blow it once, and you might as well forget it in the future. In news, especially electronic journalism, that's the name of the game.

Finally, what should Santa say to the kids, and what should he avoid? In most cases, the kids will have a list of gifts they want. Unless your club has an unlimited treasury, there will be no way to deliver on promises made, so make no promises. One of the worst things an adult can do to kids is promise and not deliver. Let Santa respond by saying something akin to "we will put it on the list and see what we can do." No hard and fast promises. Above all, keep conversations light, seasonal, and filled with "ho, ho, ho's"...and don't forget to ID at prescribed intervals.

When your operation is over, hold a critique over a cup of coffee. If you are smart, you will have recorded your "Operation Santa Claus." Use these tapes to critique the operation. Videotapes are even better. If you received TV coverage, chances are that the station probably sent a mini-cam crew to record the event. They probably recorded a lot more tape than ever reached the air, and very quick action (within 24 hours, before the cassettes are bulk-erased for reuse) might get you a dupe of the raw or unedited shoot.

Last year's Los Angeles "Operation Santa Claus" was the biggest and best to date. It was a delight to listen to and it received good press coverage from local TV, radio, and newspapers. What about this year? It's only a few days before I will know the whole story on "Operation Santa Claus 1981."

SEASON'S GREETINGS

I hope you have enjoyed this year's Christmas special. Next month, it will be business as usual. We may have some information on FCC actions against alleged (or proven) jammers, and definitely will have the last part of the SCRRBA series on voluntary frequency coordination for the 1980s. In the meantime, from those of us who write on the late shift in Los Angeles, our warmest wishes for a very Merry Christmas, Happy Chanukah, and...as the voice on the old WA6TDD repeater ID tape used to say...a Happy and Preposterous New Year. See you in 1982.

HAM HELP

I will pay someone with exceptionally good reception to record shortwave programs and send me the tapes.

Owen Aldis
282 Camino Al Lago
Atherton CA 94025

I want a Polaroid CR-9 scope camera with #33-10 (87 × 119 mm) hood, former Allied #s 561-3301 and 561-3310. Or, just the CR-9 and lens, without hood. I will pay a good price for one in working condition.

R.W. Burhans
161 Grosvenor St.
Athens OH 45701
(614)-593-8207

I need an HP-2 matching unit for the Electrospace HV-5 antenna, no longer in production. I will pay any reasonable amount.

Also, I would like to hear from any Japanese ham interested in trading Japanese stamps for US stamps.

William H. Washburn W7LJI
291 Coachman Drive
Eugene OR 87405

I am looking for a manual for a Canadian Marconi DJ 30 and also one for an RCA Carfone 150. Can anyone help?

Fred Nordstrom N4EHV
Rt. 2, Box 26
Calvin KY 40813

DEALER DIRECTORY

Phoenix AZ
The Southwest's most progressive communications company stocking Kenwood, Icom, Yaesu, MFJ, B&W, Astron, Larsen, Cushcraft, Hy-Gain, Bearcat, and more. Would like to serve you! **Power Communications Corp., 1640 West Camelback Rd., Phoenix AZ 85015, 241-Watt.**

Culver City CA
Jun's Electronics, 3919 Sepulveda Blvd., Culver City CA 90230, 390-8003. Trades 463-1886 San Diego. Call us for a low quote.

Fontana CA
Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lunar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, landmobile. **Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.**

San Jose CA
SAN FRANCISCO BAY AREA
Homebrewers' haven; tons of new and used Ham/Computer gear and components. Serving Hams since 1958. We specialize in ICOM, KLM, Mirage, Comptronix. We ship worldwide. **Tele-Com Electronics, 15460 Union Avenue, San Jose CA 95124, 377-4479.**

San Jose CA
Bay area's newest Amateur Radio store. New & used Amateur Radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santec & many more. **Shaver Radio, Inc., 1378 So. Bascom Ave., San Jose CA 95128, 998-1103.**

Denver CO
Experimenter's paradise! Electronic and mechanical components for computer people, audio people, hams, robot builders, experimenters. Open six days a week. **Gateway Electronics Corp., 2839 W. 44th Ave., Denver CO 80211, 458-5444.**

Miami FL
Amateur Radio Center, Inc. "Everything for the Amateur" Since 1960, **2805 N.E. 2nd Avenue, Miami FL 33137, 573-8383, TWX 522035.**
